One of the humblest and most lovable of men, Dr. Gillison gave himself to those in need with a generosity and abandon that will never be forgotten. One incident, characteristic of many which could be quoted about him, will serve to illustrate this point. On one occasion he showed me, rather shyly, a Chinese letter which he had received, accompanying a gift for his hospital. It ran something like this: "Dear Sir, Twenty years ago, on a terrible night in the middle of winter, you were called out in a storm to go to the help of a poor woman in labour. You went at once, although you knew quite well that the woman was far too poor to pay anything for your services. That night I was born, and from that day my mother never ceased to speak of your kindness. Now that I am able to earn money, I want to ask you to accept the fee which you ought to have had then." To Gillison that incident was just a lovely instance of a Chinaman's gratitude. To many of us it suggested a good deal more.

The death occurred on June 22 of Dr. ERNEST DEWAR CHARLES of Stanley, Co. Durham. Dr. Charles, who was only 40 years of age, was the son of Dr. John Charles of Stanley and brother of Dr. J. A. Charles, medical officer of health for Newcastle-upon-Tyne. A graduate of the Durham University College of Medicine, he qualified M.B., B.S.Dunelm in 1919, and B.Hy. and D.P.H. in 1920. He held the posts of house-physician and house-surgeon in the Royal Victoria Infirmary, Newcastle, and afterwards served on the War Pensions Committee for the

North of England area. He joined the practice of Drs. Charles, Dewar, and Benson twelve years ago, and was deputy M.O.H. for Stanley during that time. He was a vice-chairman of the Consett Division of the British Medical Association and took a keen interest in the work. He was also actively interested in the social welfare work of the district, and was chairman of the Toc H movement and of the blind welfare committee. A severe attack of rheumatic fever some years ago left permanent effects, but he was able to carry on the work of a busy practice to within seven months of his death. His ability, together with a quiet manner, gained for him the respect and esteem of all, and he will be long remembered in the district for his lovable disposition and devotion to work. Dr. Charles is survived by his wife and a son aged 12 years, with whom there is widespread sympathy in their bereavement.

Dr. JOHN ALEX. HENDERSON of Gosforth died on June 28 at the age of 46. For some years he had been a deputy regional medical officer at Newcastle-upon-Tyne under the Ministry of Health. Educated at the University of Edinburgh, he took the M.B. and Ch.B. degrees in 1915, and was for a time resident physician to the Edinburgh War Hospital at Bangour, afterwards becoming medical superintendent of the Mount Vernon Sanatorium, Barnsley. Dr. Henderson joined the British Medical Association in 1917. He contributed clinical notes to the *British Medical Journal* in 1920 and 1932 and to the *Edinburgh Medical Journal* in 1922.

Universities and Colleges

UNIVERSITY OF LONDON

Mr. R. J. Kellar, M.B., Ch.B., M.R.C.P.Ed., M.C.O.G., F.R.C.S.Ed, has been appointed from October 1, 1937, to the University Readership in Obstetrics and Gynaecology tenable at the British Postgraduate Medical School

At a meeting of the Senate held on June 23 a cordial vote of thanks was unanimously passed to Mr. H. L. Eason, M.S., F.R.C.S., for the great services which he had rendered to the University during his tenure of the office of Vice-Chancellor.

Professor L. N. G. Filon, F.R.S., and Sir Ernest Graham-Little, M.P., were reappointed members of the Court for five years from October 1.

At the meeting of the Senate on June 23 the degree of Ph.D. in Helminthology (non-clincal) was awarded to Govind Dajiba Bhalerao (London School of Hygiene and Tropical Medicine); and the degree of Ph.D. in Pathology (non-clinical) to Helen Margaret Goddard (London Hospital Medical College).

Brown Animal Sanatory Institution Committee

The Senate received the report of the Brown Animal Sanatory Institution Committee for 1936, which recorded that Mr. W. Girling Ball, F.R.C.S., had been elected chairman for 1936–7. The superintendent had continued his research on viruses on former lines, and Dr. Nathan Raw had been engaged in carrying out a research on human and bovine tuberculosis, with special reference to infections of the human body by bovine bacilli.

Address of New University Building

It has been resolved that the name of the administrative offices of the new University Building, for address purposes, shall be "University of London: the Senate House."

UNIVERSITY COLLEGE

The following awards have been made in the Faculty of Medical Sciences:

Entrance Scholarship, Margaret E. Berry. *Entrance Exhibitions*, L. N. Yhap, H. F. Melhuish. *Bayliss-Starling Memorial Scholarship (Physiology)*, A. R. Moss. *Cluff Memorial Prize (Anatomy, Physiology, Pharmacology, and Chemistry)*, R. E. O. Williams. *Anatomy* (Senior Course, gold medal), L. Rosen. *Physiology* (Senior Course, gold medal), A. G. Riddell.

UNIVERSITY OF LEEDS

The honorary degree of LL.D. was conferred on July 5 on John Kay Jamieson, M.B., C.M.Ed., Professor of Human Anatomy and Embryology at Trinity College, Dublin.

UNIVERSITY OF LIVERPOOL

At a meeting of the Council on July 6 Professor W. H. Wood was appointed Dean of the Faculty of Medicine for one year from September 1.

The following candidates have been approved at the examinations indicated:

M.D.—R. T. Bowes, J. L. Brown, Hilda M. Davis, D. O. Hughes, K. W. Stroude.

M.B., CH.B.—[1] [3] [4]G. E. O. Williams, [2] [3]R. R. Hughes. *Part III:* A. M. Abrahams, J. de Bastarrechea, S. Bender, D. Boyars, W. E. G. Bradford, A. Brooke Bateman, K. W. Cameron, Sheila Carmichael, L. H. Chandler, R. I. Cohen, K. A. Colenso, K. W. Evans, J. G. Fox, Constance M. Frazer, T. C. Gray, [3]A. S. Hall, Elsie O. Hughes, H. Hughes, T. S. Jones J. Kay, [3]A. T. Leggate, M. Libman, G. B. Manning, R. Marcus, Doreen M. Martin, R. S. Riley, W. A. M. Robinson, J. P. G. Rogerson, P. J. Rooney, J. M. Russell, Henrietta Sloan, A. C. Smerdon, Gwenda Vaughan, J. Wajnerowicz, Evelyn M. Williams, Margaret E. Williams, H. Zalin. *Part II:* H. G. A. Almond, H. Alstead, H. Angelman, C. T. Baynes, Patricia M. Bennett-Jones, A. L. Black, E. J. Bowmer, A. R. Bracey, D. W. Bracey, H. Braslavsky, B. H. Brindle, H. Buckley, A. E. Burton, B. Carruthers, J. L. Chisnall, [3]W. H. R. Cook, J. W. Crowther, G. H. Daglish, H. Dakin, R. B. Davies, J. Donnelly, Mary W. Gaskell, K. B. Gibson, J. Griffith, E. L. Hamm, W. J. Hay, Anne F. M. Heaney, D. R. Holden, R. S. Holgate, E. P. Houghton, G. O. Hughes, [4]D. A. Hunt, Brenda M. Jones, [4]Iola L. T. Jones, M. P. Jones, P. Jones, Helen Kay, R. J. Keating, J. C. Kee, J. C. Kitchen, E. Leather, J. M. Marchant, J. Mills, J. Moroney, A. Nachmanovitz, S. Newman, J. H. Newmark, P. J. O'Flynn, E. N. Owen, [3]R. A. C. Owen, J. L. Patton, B. I. Phillips, Hilda C. Podmore, J. G. Pritchard, W. Pritchard, [4]E. B. Riding, D. J. Roberts, G. I. Roberts, R. H. Roberts, G. M. S. Ryan, [3] [4]E. L. Salingar, G. Sanderson, Joyce M. Scholefield, [4]V. K. Summers, R. J. D. Temple, G. R. Thorpe, G. C. Tweedie, Lucy H. E. Walker, R. Watson, J. H. D. Wetherell, [4]R. H. White-Jones, A. R. Whitman, [4]A. H. Williams, [4]C. J. Williams, Gwendoline Williams, [4]I. P. Williams, Joan S. Wood, E. G. Wright, [4]G. Wynne-Griffith, M. Wynroe. *Passed in Individual Subjects:* G. L. Manson (Forensic Medicine and Toxicology), R. H. M. Stewart (Public Health). *Part I:* [4]C. D. Alergant, G. E. Badman, Frances E. Brierton, R. F. Browne, E. H. L. Cook, Margaret Edge, R. M. Evans, H. B. Forrest, [4]D. M. I. Freeman, Thelma R. Gaunt, C. M. Gregory, G. C. Griffiths, J. Harders, F. Hedley, Bessie Howarth, H. Ingham, [4]C. T. Jenkins, W. Kulke, [4]A. L. Latner, P. C. Lawson, Pearl Lyons, D. H. McCormack, [4]Sylvia Makin, Eileen E. V. Martin, R. J. Miller, G. W. H. Millington, [4]J. D. Muir, P. J. O'Flynn, R. J. Parry, J. L. Patton, Geraldine M. H. Paul, [4]Eleanor M. Pearson, L. G. Poole, A. G. Porterfield, T. Price, V. A. Rogers, C. Rowlands, H. J. Shuttleworth, C. R. Sluming, H. J. H. Soulby, W. O. Spence, Lucy M. Sutcliffe, Catherine S. Thomas, [1] [4]G. O. Thomas, Megan E. Thomas, Joan P. Thomson, G. R. Thorpe, J. N. Threlfall, [4]Olivia S. Turner, J. A. Wethered, J. H. D. Wetherell, A. G. Williams, K. M. Willis. *Passed in Individual Subjects:* J. L. Chisnall, J. A. Gillet, R. R. Knowles, Kathleen Pugh-Jones (Pharmacology and General Therapeutics).

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Part B:* M. J. Brady, J. Courtney, T. D. J. O'Farrell, J. A. Ross.

D.P.H.—E. Agius, R. T. Bowes, [4]A. Dodd, Bessie Dodd, J. G. Hailwood, Joy C. Lowe, P. Somasundram, E. A. Stilon. *Part I:* G. R. Griffith, S. M. Laird, P. Somasundram.

DIPLOMA IN TROPICAL MEDICINE.—J. Yofe.

DIPLOMA IN TROPICAL HYGIENE.—G. G. Ludlam, S. H. R. Syed, Luise Wislicki.

[1] First-class honours. [2] Second-class honours. [3] Distinction in Surgery. [4] Distinction in Obstetrics and Gynaecology. [5] Distinction in Forensic Medicine and [illegible] in Public Health. [7] Distinction in Patholo[illegible]rmacology and General Therapeutics. [8] With distinction.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

M.D.—J. R. P. Edkins.

FINAL M.B., CH.B.—L. S. Anderson, J. C. Babbage, I. W. Ball, R. S. A. Beckett, G. H. H. Benham, Muriel L. Bennett, M. J. Blank, T. Dinsdale, J. H. Ferguson, J. H. France, Rosaline Green, A. B. Hamer, R. S. P. Hawkins, F. G. Hibbert, W. S. Holden, T. Holme, W. Ingman, Monica M. Job, Katharine I. Liebert, J. R. Monks, H. N. Osborne, Nydia E. Panton, A. F. Pearson, W. H. Purves, W. A. Robson, Nina Shtetinin, T. S. Stewart, F. Stratton, N. Whalley. *Part I (Forensic Medicine and Hygiene and Preventive Medicine):* N. Altham, J. N. Appleton, Muriel I. R. ApThomas, H. B. Austin, T. M. Brand, W. W. Burnett, T. E. A. Carr, J. E. Coates, A. E. David, D. B. H. Dawson, T. B. S. Dick, A. M. Dickson, G. Garmany, A. B. Hamer, K. Harrison, Kathleen

M. Henderson, A. G. Heppleston, C. P. Heywood, Barbara M. Jessel, F. A. Langley, N. Levy, L. Linnell, D. Longbottom, Jean Mason, J. C. Mellor, A. Morgan-Jones, S. Mottershead, T. H. Norton, Mary B. Oakden, Lilian P. Parry, J. K. Rowson, E. Saunsbury, M. R. Tomlinson, T. B. Whitehead, W. W. Wilson, Frances T. Wright. (*Pathology and Bacteriology*): P. N. Holmes, D. N. Kiff, Constance M. F. Lyth, J. C. Ramsden, J. F. Rickards, H. E. Thackray, E. J. Yates. (*Pharmacology*): J. G. Atherton, A. P. Bates, T. Brittain, J. B. Brownlie, E. F. Burndred, Olive I. Elkin, J. Gregory, J. E. Horocks, A. Manch, J. E. Schofield, W. P. Sweetnam, G. K. Tutton.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—*Part I:* Muriel Hughes.

UNIVERSITY OF ABERDEEN

The following degrees were conferred at a graduation ceremony on July 7:

HON. LL.D.—Theodore Shennan, M.D., F.R.C.S.Ed., Emeritus Professor of Pathology in the University of Aberdeen.

M.D.—*H. W. Fullerton, *E. J. R. Leiper, Helen M. Jardine, J. Leiper, J. S. Walker, D. E. Wilson (*in absentia*).

CH. M.—*J. F. Philip.

M.B., CH.B.—†‡E. K. Cruickshank, †J. G. Macarthur, †A. Macdonald, †R. F. Macdonald, †J. A. F. McLean, †*D. Matheson*, †*E. E. P. Murray*, †A. W. Souter, A. S. Ashby, H. W. Balch, J. A. Barclay, E. B. Bright, W. M. Burgess, R. McN. Cadenhead, A. S. Cameron, Margaret D. Cameron, R. W. Catto, Margaret R. Clark, Enid M. M. Clow, A. Coull, J. B. Cruickshank, D. J. Cusiter, A. M. Davidson, D. J. Dawson, L. H. Duthie, *A. H. Emslie-Smith*, J. K. Farquharson, Mary I. Forbes, F. W. Fyfe, E. N. Gauld, M. S. Glassman, Jamesina Gordon, R. M. Gordon, D. Harkins, W. Herbert, E. A. Horne, J. Innes, A. Jamieson, Phyllis D. Leslie, C. M. Liddell, J. G. T. Lunn, R. J. L. MacBean, R. McDonald, J. F. Mackay, J. A. McKenzie, Jessie M. McKenzie, A. McKerlie, J. M. McKiddie, G. S. M. Mackintosh, J. M. Mair, P. Matheson, Isabel M. Mathieson, G. N. Miller, S. J. H. Miller, A. Milne, L. McD. E. Milne, Marian B. Milne, P. C. Mitchell, R. D. Monteith, J. J. T. Morrison, A. F. Murray, F. S. Rae, D. D. Reid, G. L. Ritchie, Margaret M. Robinson, J. Ross, G. Sangster, W. A. McD. Scott, W. Selbie, Jean McK. Sheach, Elizabeth M. M. Simpson, J. Slorach, W. Smith, Florence Stephen, G. A. Stephen, I. C. Stephen, *H. Tatton*, *Hilda M. Teunon*, *Elsie J. Thomson*, W. J. F. Treacher, G. B. Will, Isabella M. Will, S. C. Wright, A. G. B. Young.

D.P.H.—W. J. Hogg.

D.Sc.—Allan Watt Downie, M.D., Henry Edward Shortt, M.D., Lieut.-Colonel I.M.S. (*in absentia*).

* Awarded Honours for Thesis. † With second-class honours. ‡ Passed Final Medical Professional Examination with Distinction.

QUEEN'S UNIVERSITY OF BELFAST

At a meeting of the Senate held on July 2 Dr. G. C. Lowry, professor of midwifery since 1920, was appointed to the combined Chair of Midwifery and Gynaecology.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

At the later summer commencements, held on June 30, the following medical degrees were conferred:

M.D.—A. J. O'Connor, J. B. Patrick, H. T. Ryan, W. C. Sloan.

M.B., B.CH., B.A.O.—M. C. Brough, H. M. Carson, F. J. B. Convery, E. R. N. Cooke, C. Cunningham, G. C. Donald, R. W. Duncan, C. Eppel, C. J. S. Flood, E. G. Fox, J. E. Gillespie, W. Hayes, F. C. Heatley, J. C. Lambkin, G. N. MacFarlane, H. F. T. MacFetridge, J. H. Mitchell, C. Mushatt, A. D. Parsons, (*in absentia*), R. Pollock, H. FitzG. Sloan, J. A. Strong, Jasmine Taylor, R. E. Taylor, H. J. Walker, W. J. G. Warwick, M. C. Wood.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A quarterly Council meeting of the Royal College of Surgeons of England was held on July 8, with the President, Sir Cuthbert Wallace, Bt., in the chair.

Sir Cuthbert Wallace, Bt., was re-elected President. Mr. Victor Bonney was re-elected Vice-President, and Professor G. Grey Turner was elected Vice-President for the ensuing year.

Mr. C. H. Fagge, Mr. W. Sampson Handley, and Mr. C. P. G. Wakeley were admitted to the Council.

Under the Moynihan Bequest not less than three, or more than five, lectures on the results of research in its application to surgery shall be given in alternate years by a lecturer who shall be styled the Moynihan Lecturer.

Lecturers

The following lecturers were appointed for the ensuing year:

Hunterian Professors.—Mr. P. B. Ascroft, one lecture on an Experimental Study of the Surgical Treatment of Arterial Hypertension; Mr. H. J. B. Atkins, one lecture on Chronic Mastitis; Dr. J. I. Munro Black, one lecture on the Lympho-epitheliomata; Mr. R. C. Brock, one lecture on the Pathology, Diagnosis, and Treatment of Intrathoracic New Growths; Mr. Maxwell Ellis, one lecture on the Function of the Bronchial Tubes; Mr. T. Stewart Heslop, one lecture on an Experimental Study of the Neurogenic Origin of Peptic Ulceration; Mr. J. Cole Marshall, one lecture on Detachment of the Retina and the Modern Operative Treatment; Mr. T. W. Mimpriss, one lecture on the Histology and Treatment of Imperfect Descent of the Testis; Mr. Reginald T. Payne, one lecture on Cancer of the Stomach as a Surgical Problem; Mr. Harold Rogers, one lecture on the Gastroscopic Appearances of the "Normal" Gastric Mucosa and its Constitutional Variations; Mr. T. F. Todd, one lecture on Rectal Ulceration following Irradiation Treatment of Carcinoma of the Cervix (Pseudo-carcinoma of the Rectum); Mr. William E. Underwood, one lecture on Recent Observations on the Pathology of Hydronephrosis.

Arris and Gale Lecturer.—Dr. John Beattie, three lectures on subjects relating to Human Anatomy and Physiology.

Erasmus Wilson Demonstrator.—Mr. L. W. Proger, six demonstrations on the Pathological Contents of the Museum.

Arnott Demonstrator.—Mr. A. J. E. Cave, six demonstrations on the contents of the Museum.

Mr. L. W. Proger was re-elected Pathological Curator of the Museum for the ensuing year; Sir Frank Colyer was re-appointed Honorary Curator of the Odontological Collection for the ensuing year; Mr. C. J. S. Thompson was reappointed Honorary Curator of the Historical Collection.

The Hallett Prize was awarded to Alexander James Innes, and the eighth Macloghlin Scholarship to David Somerset Short of Bristol Grammar School.

Mr. Constantine Innes Pocock was appointed Charles Ryall Library Research Assistant for one year from October 1.

Dr. *David Slome* was reappointed as a Mackenzie Mackinnon Research Fellow.

The following assessors were appointed for the Primary Fellowship Examination to be held overseas during the coming year: Professor F. Wood-Jones and Dr. C. H. Kellaway (Melbourne); Professor A. N. St. G. Burkitt and Professor W. H. Davies (Sydney); Professor W. R. Gowland and Professor J. Malcolm (Dunedin); Lieut.-Col. F. J. Anderson, M.C., I.M.S. and Lieut.-Col. S. L. Bhatia, M.C., I.M.S. (India); Professor D. E. Derry and Professor Gleb von Anrep (Egypt).

Diplomas

A Diploma of Membership was granted to William Bradford Foster.

Diplomas were granted jointly with the Royal College of Physicians of London as follows:

DIPLOMA IN PUBLIC HEALTH.—L. J. Bacon, T. E. Jones-Davies, J. MacC. Kilpatrick, A. E. Lorenzen, C. Mani, J. N. Matthews, Doris Onions, T. B. Patel, H. E. Raeburn.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—M. B. Brody, Hilda M. Capes, Bridget Coffey, E. C. Dax, T. R. C. Fraser, J. B. Giffen, W. G. Glassco, Joan E. Greener, A. Harris, G. T. James, C. A. Keane, J. S. Knox, E. H. Larkin, A. B. Monro, K. N. H. Rizvi, K. Soddy, J. T. W. Spiridion-Kliszczewski, C. E. H. Turner, G. P. B. Whitwell.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.—G. N. Barker, G. A. Fraser, K. H. Hakim, M. Jackson, J. A. Kersley, G. P. Rayen.

The Services

HONORARY PHYSICIANS TO THE KING

The King has appointed Colonel H. C. Buckley, I.M.S., and Colonel D. C. V. Fitzgerald, M.C., I.M.S., as Honorary Physicians to the King, in succession to Major-General Sir Cuthbert A. Sprawson, C.I.E., I.M.S., and Major-General C. W. F. Melville, C.B., I.M.S., who have retired.

HONORARY SURGEON TO THE KING

Surgeon Rear-Admiral F. J. Gowans, R.N., has been appointed Honorary Surgeon to the King in the vacancy caused by the retirement of Surgeon Vice-Admiral Sir R. W. Basil Hall, K.C.B., O.B.E.

HONORARY SURGEON TO THE VICEROY

Colonel S. G. S. Haughton, C.I.E., O.B.E., I.M.S., has been appointed Honorary Surgeon to the Viceroy and Governor-General of India.

Medical Notes in Parliament

In the House of Lords on July 13 the Royal Assent was given to the Physical Training and Recreation Act, the Trade Marks (Amendment) Act, and the Methylated Spirit, Sale by Retail, (Scotland) Bill. The Physical Training Bill had received a third reading on July 12. Also on July 13 the Local Government Superannuation Bill was read a second time, and the Cinematograph Films (Animals) Bill passed through committee.

In the House of Commons on July 12 Mr. Ramsbotham moved the second reading of the Milk (Amendment) Bill, which, he said, extended the Milk Act, 1934, as amended by the Act of 1936, for a further twelve months. The Bill was merely a continuing Bill, and he hoped that a policy of a more permanent and far-reaching character might have time to mature. The Bill was read a second time.

The Local Government Superannuation (Scotland) Bill passed the report stage and was read the third time in the House of Commons on July 13.

Marriage Bill

On July 7 the House of Lords went into committee on the Marriage Bill. Lord SALTOUN initiated the debate on Clause 1, which, as received from the House of Commons, provided that there should be no divorce within five years from marriage. He moved to insert the words "except as otherwise expressly provided in this Act." He said his amendment was necessary in order to make room for a subsequent amendment standing in his name. This subsequent amendment sought to enact that if one spouse, against the will of the other, refused to permit the conception or birth of a child without good reason, this should be a ground for divorce without delay.

Lord Saltoun's amendment was negatived.

Lord JESSEL moved to substitute three years for five as the period after marriage within which no petition for divorce could be presented to the High Court. A long debate followed and the amendment was eventually agreed to, and Clause 1 as amended was added to the Bill.

INSANITY AS GROUND FOR DIVORCE

On Clause 2 (Grounds of petition for divorce) the chairman, the EARL OF ONSLOW, informed the committee that he had received a manuscript amendment by Lord Dawson of Penn to substitute the words "believed to be incurable" instead of the word "incurably" in the provision of the Bill that unsoundness of mind which had been continuously under care and treatment for at least five years immediately preceding the presentation of the petition should be a ground for divorce. Before discussing Lord Dawson's amendment the committee considered one by Lord Elton to omit the subsection of Clause 2 dealing with insanity. He said this paragraph alone permitted divorce for a misfortune. The word "incurably" was a "question-begging" epithet, and he assumed that Lord Dawson in his manuscript amendment recognized that it was very difficult to maintain the word "incurably." The tendency of modern psychology was towards recognizing that scarcely any mental disease should be regarded as incurable. The Bill would pronounce a final sentence that the sufferer would have no hope of being cured. It was wrong that there should hang over the dark approaches of insanity a threat that if the worst should fall the sufferer would be stripped of all he valued most.

The ARCHBISHOP OF CANTERBURY supported the amendment. He imagined Lord Dawson had accepted the fact that they could not really speak of mental disease as being incurable. The adoption of the clause would result in retarding the recovery of those who were curable, and would sometimes upset the balance of those who were liable to become insane.

Lord DARCY DE KNAYTH pointed out that the report of the Royal Commission recommended that incurable insanity could only be a ground for divorce when the age of the insane person was, if a woman, not over 50, and if a man, not over 60 years. The last recommendation would exclude cases of senile dementia. There was nothing to that effect in the Bill.

MEDICAL OPINION

Lord DAWSON OF PENN said if there were not differences between experts there would be no progress in the world. It was a mistake to suppose that medical experts always differed. On essential subjects there was more general agreement in the medical profession than in any other. It was common ground that this particular group of cases demanded merciful consideration because in most instances the matter was not one of fault but of misfortune. That statement was not true in the case of chronic alcoholism producing dementia or in the case of syphilis, but broadly speaking misfortune came into the question of insanity more than into the question of adultery and cruelty. Speeches had been made from which one would think there was no suffering partner in the case of insanity, but anyone who had an opportunity of studying insanity in the homes would often conclude that far more sympathy was to be extended to the suffering spouse who felt acutely than to the patient who felt less acutely.

The proposed ground for divorce in Clause 2 could not be considered without regard to Clause 3, which provided that the insane patient must have had continuous treatment in some institution for five years. That was a great protection. A fair consensus of opinion was that the majority of patients who had been under continuous treatment for five years did not recover. To assert that anything in the world was incurable was not a wise statement from a scientific man, and he would propose to substitute "one who is believed to be incurable." In the first year of treatment for insanity the prospects were very good. There was a big drop in the prospects between one year and two years, and between three and four a greater drop. After five years the number who recovered was very small. Was it not the duty of that House to say, in justice to the suffering spouse, that after five years, when the prospects of recovery for the patient were so small, that spouse should have a chance of relief? It was not made compulsory. It should be remembered that the majority of people with whom the Bill was concerned lived in houses of only a few rooms, and therefore in cases of cruelty or insanity, whether caused by drunkenness or drug addiction, the hardship pressed more heavily.

The five-year clause had been put in the Bill after advice from experts, and that advice was right. Cases of shell-shock in the war were on a totally different footing from cases of insanity which resulted from organic and structural disease. For example, there had never been a case when the arteries of a man, which were getting harder and harder, had recovered. Similarly, there were definite structural causes of insanity which in their very nature must be incurable. It was important to distinguish between such cases and the large group of functional cases, which, if they were put under treatment, would most of them be cured in much less than five years. The idea that a prospect of divorce would affect an insane person was wrong. In the majority of cases where persons had been under continuous treatment for five years the range of mental vision contracted.

Lord SALISBURY said they could not contest with Lord Dawson any matter of medical opinion, but he had put before the House a case in which the majority of insane persons would not recover, suggesting that a substantial minority would undergo the risk of divorce. It did not follow that because a man was insane he had not the most acute feelings.

Lord ADDINGTON said he had had experience with a mental hospital in the visiting and discharging of patients. Medical science had progressed in the twenty-five years since the Royal Commission, and his hospital hoped to be able to discharge as cured an increasing number of patients even after five years. Lord ELTISLEY remarked that the question of lunacy had been carefully considered by the Royal Commission and debated at great length in the House of Commons.

The view of the House of Commons had been that the paragraph under discussion should be inserted in the Bill.

Subsection (*d*), providing for divorce for incurable insanity after at least five years' treatment, was then accepted by 95 votes to 31.

Lord DAWSON then explained that on the advice of his legal friends he would postpone until the report stage his amendment to substitute another form of words for "incurably" in order to permit redrafting. He also added that he would not move an amendment in which he had intended to add to the grounds of divorce after Subsection (*d*) "or has during that period been subject to recurrent attacks of insanity." He said that in cases of cyclical insanity, dangerous as these people were to the happiness of their homes, he was afraid it would be true that when the patient came back from a period of insanity and re-entered the home he would suffer as a result of knowledge that he might be divorced.

HOMOSEXUALITY AND DIVORCE

Lord DAWSON moved an amendment providing that a petition for divorce might be presented on the ground that the respondent had since the celebration of the marriage been guilty of the practice of homosexuality. He said that some explanation was due from him in moving this addition. Homosexuality was now looked on as a pathological condition. He was not at all sure that in the future it might not be regarded as an insufficiency disease, and although it was true that the law must take cognizance of homosexuality and punish it in order to act as a preventive to potential offenders, the more reasonable view was gradually being adopted that it, at any rate, had one foot in the realm of disease and was not wholly in the realm of crime. He was not disputing the fact that the law must take serious cognizance of this offence, but he urged that this was an occasion for recognizing, with advancing knowledge, the increasing tendency to regard it as a pathological process, which concerned those who had to deal with disease. For the purposes of the Bill it would be entirely wrong to use any word which confined homosexuality to one sex. It was really time that there should be equality of treatment between men and women. For that reason, also, the insertion of this special paragraph was justified.

This particular offence was quite compatible with excellent qualities of mind and character. But such people would frustrate the purpose for which marriage existed, and it would be a grave injustice to recognize any marriage in which homosexuality turned out to be existent in either one of the parties. When that was discovered it ought to be a ground for divorce. As to cure, they were only on the brink of this question. For those who had a scientific interest it was a study of extraordinary fascination, and there was no doubt that a realm was being opened up which would enable more help to be brought to these people, provided they could be caught in the early stages. Whether they could be in later life he very much doubted.

Lord ELTISLEY said he did not fully understand what the amendment meant or what its ramifications were, or how it was to be carried out in practice by the courts of law if it was passed. What was clear, however, was that the purpose of the amendment was to put both sexes on the same footing with regard to homosexuality as a ground for divorce. He resisted the amendment because this recommendation was not one made by the Royal Commission, and it was dangerous to endeavour to introduce a new ground of divorce of this character into the Bill.

Lord DAWSON begged their lordships not to decide by the knowledge of years ago. If they were going to make a change on a matter like this, surely they must take cognizance of the progress in knowledge that had taken place in the last twenty-five years. If there was one thing that had been established in our legislation of recent years it was equality of the sexes, and this ought to cut both ways.

Lord ATKIN said he would not like it to be thought that the House of Lords rejected the more modern application of science as put forward by Lord Dawson without some reasoned objection to it. To begin with, he thought that it was not correct to say that these cases—Lord Dawson did not say so—were the result of something in the nature of disease. It was quite certain in one's experience that they were the result of wicked impulses which were capable of being controlled. Like other impulses of the kind they could be checked by advice and by resolution, and they did not appear to him to be of the nature of a permanent infirmity that was always likely to affect the married life. The real answer probably, at the present moment, was that this was a subject which required very careful examination. If some time or other a select committee or a departmental committee considered this subject in all its branches the result might be a very valuable report upon which the criminal law and the civil law might very well be amended. At present it would be a mistake to send this amendment to the House of Commons with the discussion that would be likely to arise about it.

The amendment was negatived.

DRUG ADDICTION

Lord DAWSON moved to insert as an additional ground for divorce:

> "is an habitual drunkard, or is an inveterate drug addict. For the purposes of these paragraphs a signed certificate will be required to be given in each case by two medical men, at least one of whom belongs to a panel of names approved by the Home Secretary on the nomination of the Royal College of Physicians, London."

Lord Dawson said that nothing broke up a home more than habitual drunkenness on the part of a woman or of a man, or drug addiction, and under the present law there was no power to cure such persons. Unless they were certified insane they could not be treated. If they became insane and were certified, then within a few weeks their addiction was sufficiently relieved for them to demand their release from certificate, and back they went to their addiction.

Lord BERTIE OF THAME moved as an amendment to Lord Dawson's to add:

> "The expressions 'habitual drunkard' and 'inveterate drug addict' mean a person who by habitual drinking to excess of alcoholic liquor or of addiction to drugs, as the case may be, is (*a*) at times dangerous to himself or to others or the cause of reasonable apprehension of such danger, or (*b*) incapable of managing his own affairs. The expression 'drugs' means drugs to which Part III of the Dangerous Drugs Act, 1920, applies."

Lord MERSEY said the question raised by Lord Dawson had been fully discussed in the House of Commons, which had decided that it was not desirable. Lord CECIL OF CHELWOOD pointed out that the provision of the Bill regarding insanity insisted that the insanity must be believed to be incurable, and that the person must have been under treatment for five years. No such provisions were suggested by Lord Dawson, and there was no definition of what was an habitual drunkard or an inveterate drug addict. Lord ELTISLEY did not think that it would be to the advantage of the Bill to insert the words proposed by Lord Dawson. Drunkenness was often accompanied by cruelty, and anyone who could prove that he or she was subject to habitual cruelty would be entitled to a decree. If the drunkenness was continual, even if the man was not actually cruel, he would be guilty in law of constructive desertion, and the injured spouse would be able to obtain a measure of relief provided the cruelty was continuous for three years.

Lord Dawson's amendment and the addition proposed by Lord Bertie were both negatived.

On Clause 5 (Decree of judicial separation) Lord ATKIN moved to insert words to provide that one ground for judicial separation should be a failure to comply with a decree for restitution of conjugal rights, and also that a decree might be granted on any grounds on which a decree for divorce *a mensa et thoro* might have been pronounced before the Matrimonial Causes Act, 1857. That would cover any attempt at rape and so forth, and also include cases of gross indecency, and would probably cover general cases of homosexuality. The amendment was agreed to.

On Clause 6 (New grounds for nullity) Lord CECIL OF CHELWOOD moved an amendment to Subsection 1 (*b*). This

subsection provides that a marriage shall be voidable on the ground that either party to the marriage was at the time of the marriage of unsound mind, or was at the time of the marriage or had been within twelve months of that time placed in an institution or under guardianship under Section 3, Section 6, Section 8, or Section 9 of the Mental Deficiency Act, 1913, or was at the time of the marriage subject to recurrent fits of insanity or epilepsy. Lord Cecil moved to provide that these causes should apply within twelve months after marriage. It would be a reasonable extension to the grounds of nullity to say that where the unsoundness became clear and evident within a year after marriage it might be presumed that the party was at the time of marriage not in a mental condition to give true assent. As he read the Bill it did propose that where one of the parties to the marriage was placed under restraint under the Mental Deficiency Act that should be a sufficient ground for a declaration of nullity.

Lord ATKIN said Lord Cecil's suggestion was contrary to principle. Nobody ever heard of nullity except on a ground which was existent at the date of marriage. Madness might arise twelve months after the marriage through a cause which had nothing in the world to do with the conditions at the marriage; it might be the result of childbirth. Lord DAWSON said mental disease might be so latent that it might be an unknown ground of suspicion. If in consequence of the marriage the symptoms were manifest and fully developed six or eight or nine months afterwards, it was often then possible to say that the vague symptoms of the earlier time had really been the beginning of a disease. The bulk of scientific opinion would be with Lord Cecil on that issue, but to establish the case the court would require to have before it scientists who would be able to give evidence whether that were true in the particular case or not.

Lord CECIL asked whether, before the report stage, they could not agree to accept a provision saying that the fact that one of the parties went mad within a year should be prima facie evidence which could be rebutted of unsoundness of mind at the time of the marriage. Lord ELTISLEY promised to consider the suggestion, and Lord Cecil withdrew his amendment.

On the motion of Lord GORELL paragraph (*b*) of Clause 6 (1) was replaced by a modified provision running as follows:

> "(*b*) that either party to the marriage was at the time of the marriage of unsound mind, a mental defective within the meaning of the Mental Deficiency Acts, 1913 to 1927, or subject to recurrent fits of insanity or epilepsy."

The committee negatived an amendment moved by Lord DAWSON OF PENN to insert the following new paragraph:

> "(*c*) that either party to the marriage has been within twelve months prior to the time of the marriage guilty of the practice of homosexuality."

Lord Dawson postponed to the report stage the question of amendments dealing with the communicability of venereal disease.

The committee stage was completed.

Attack on Animal Diseases

On June 29 the House of Commons debated in committee the financial resolution on which the new Agricultural Bill will be founded.

Mr. W. S. MORRISON, in moving the resolution, said that the Government's proposals included the inauguration of an attack on disease in flocks and herds of animals and in poultry on a scale greater than had ever been attempted in this country. It was proposed to use for this purpose the machinery of the Diseases of Animals Acts. An essential feature of that machinery was control at the ports, and another was the designation of areas in the country which were infected and the making of orders controlling the movement of animals within those areas and out of them into other parts of the country. In this way various diseases had been tackled with success in the past. The position with regard to tuberculosis, to which other machinery had been applied, had, however, tended to deteriorate. That was due partly to the increased mobility of modern life. A greater number of animals had had to be transported from one part of the country to another, and there was a development of dairying on a "flying herd" basis, where a man bought cattle which travelled long distances, and which came from a source of whose freedom from infection he was ignorant. The Gowland Hopkins Committee reported in 1934, and estimated that 58 per cent. of the dairy cattle leaving herds were disposed of on account of disease; that the average productive life of dairy cattle was under four and a half years, or half what it should be; and that 40 per cent. of the cows were infected with tuberculosis in various degrees, and about the same proportion had contagious abortion. The total burden of the diseases among all kinds of livestock had been estimated at about £14,000,000 a year.

PROPOSED CENTRALIZED VETERINARY SERVICE

It was clear that the eradication of disease, if they were only half successful, would be a most valuable service to agriculture. So far they had tackled it in two ways. There was the Tuberculosis Order of 1935 under the Diseases of Animals Act. That prescribed rules whereby cattle which were very badly infected with tuberculosis, so as to be visibly infected and dangerous, might be slaughtered and compensation paid. But that Tuberculosis Order did not touch cattle which could not be so described but were none the less reactors to the tuberculin test and might be conveyors of the disease. The second way in which they had tackled it had been by legislation directed to the purity of the milk supply as a public health service. That had been administered by local authorities in England and Scotland with varying results. It was now proposed to tackle this immense problem as what it was—namely, a problem of the diseases of animals—by the diseases of animals machinery, by a single island service of veterinary officers for the purpose. It was not a problem which farmers themselves could possibly solve. It was the result of many generations of neglect, and one generation of farmers could not provide a cure for it. But farmers could, if this service was provided for them and they co-operated with it, rid themselves by degrees of a heavy burden and toll of disease.

Nor could this problem be solved under the present system, whereby local authorities, with their varying resources and standards, were grappling with it. It was not the men but the system which was at fault. What was wrong was the varying standards of administration, very often due to varying rateable values and resources. As a result of that variation they found that good work which had been done in one county might be hampered and destroyed by less good work in an adjoining one. The division of areas by counties was not the same thing as the designation of areas on account of the amount of disease or absence of disease in them. A second fault in the present system was that the powers of local authorities, regarding the matter as a milk problem, were inadequate. The surest way of getting tubercle-free milk was to get cows free from tubercle in the first instance. The attack on tuberculosis had hitherto been carried out in detachments, with a local force sometimes getting out of touch with its neighbour and liable from that cause to encirclement by the enemy and to frustration. What was needed was not so much a change in tactics as a more comprehensive strategy. The Government's proposals sought this more comprehensive stategy by the creation of a centralized veterinary service for the whole island to combat the diseases of animals and of poultry in all their manifestations.

POSITION OF VETERINARY OFFICERS

This was largely a veterinary problem, and veterinary opinion was in favour of the proposals. Some apprehensions had been expressed because the Government was setting up this State centralized service of veterinary officers, that in some way part-time practising veterinary surgeons would have their living interfered with, but there was no ground at all for that fear. Where veterinary surgeons were now employed on a part-time basis by local authorities it was certain that they would have to employ them on the same basis to carry out tests and do other work similar to that which they were doing now. Indeed, it was true to say that by making the

agricultural community more conscious of the importance of disease among livestock, there was a greater prospect of these practitioners finding their services utilized. He hoped to see from this a rise in the whole status of the veterinary profession in this country which would be of lasting benefit to agriculture and the nation.

Mr. T. WILLIAMS said that the Gowland Hopkins report, which was published in 1934, pointed out that 40 per cent. of our dairy cows were reactors, and that there were no signs of diminution. The life of a dairy cow was about four and a half years when it very well might be eleven or twelve years, and the annual loss due to the death of dairy cows sold for the meat market lest they contracted tuberculosis in an acute form was about £3,000,000. The Opposition wanted to see in existence as soon as possible a national veterinary service with full power to act, so that no county which ignored its responsibilities would affect adjoining counties in which people were doing their best to clean up their herds.

NEW ATTESTED HERD REGULATIONS

Mr. W. ROBERTS said they all welcomed the proposals for disease control, but he was rather surprised at the Minister's remarks about the reorganization proposed in regard to the veterinary services. There were at present several types of authority or organization which might in some cases deal with the matter. The local authorities had up to now had to carry out the administration of the Milk and Dairies Order. Was the administration of that Order under the 1922 Act to be taken over from the local authorities and centralized under veterinary officers, who were to carry out the work on behalf of the Government direct? He took it that it was the new services under this particular resolution which were to be carried out by a staff of veterinary officers directly responsible to the Ministry. On the whole he welcomed that, and he hoped that the new attested herd regulations would be more effective than the old ones. Under the attested herd scheme the main encouragement was the 1d. a gallon which the farmer might get on his milk, but there were many farmers in the high-lying districts who concentrated on breeding stock, and some encouragement should be given to them to clear their herds of tuberculosis.

Mr. PRICE was glad the Government proposed to deal with bovine tuberculosis on the basis of areas. He was also glad that the veterinary services were to be brought under a more central control, but there was an invaluable private veterinary service in this country which was of tremendous assistance to farmers, and which he hoped would not be jeopardized.

Mr. HOPKIN said it was not possible now to provide attested milk for the school scheme because there was not enough. The Minister ought, as soon as possible, to see that milk of the best quality and the highest purity was obtained by the school children before anyone else. He was glad that this scheme was joined up with a planned attack on contagious abortion, but the amount to be spent on that was far too little. Sir FRANCIS ACLAND said he believed he was acquainted with members of the medical profession who would, with the present standard of knowledge existing, be capable of preparing—not a live vaccine, which was itself dangerous—but a dead inoculum, which could be inoculated into calves at birth and would protect them from any risk of tuberculosis. If that system could be worked out and made generally applicable they could get rid of tuberculosis within one generation of cattle.

VETERINARY SERVICES IN SCOTLAND

Mr. HENDERSON STEWART moved an amendment to retain for Scotland the general autonomy in administration which under the Scottish Office was now enjoyed, and to preserve the present high standard of veterinary services in Scotland. He said that the Government's proposal would take from the local authorities in Scotland and the supervision of the Scottish Office the various services now administered in Scotland under a series of different Acts, including the Milk and Dairies Act, the Attested Herd Scheme, the Milk (Special Designation) Order, the Meat Inspection Act, etc. These services were of a much higher standard, he believed, than was to be found south of the Border. Under the Milk and Dairies Act, 1914, the duty was laid on local authorities in Scotland to carry out at least one clinical inspection per annum of the dairies in the country. Local authorities in this country had no such duties imposed upon them; they had the power, which they might use as they desired. Since 1914, under the continual pressure of the Scottish Office and of different Secretaries of State, the annual inspection had been multiplied by three, so that in 75 per cent. of local authority areas in Scotland there were no fewer than three inspections per annum of the cows and dairies. To carry out that inspection the Scottish Border local authorities employed forty-two full-time veterinary surgeons and fifty-eight part-time veterinary surgeons. The process of the cleaning up of herds had advanced in Scotland to a very considerable extent. It would, he thought, be impossible to bring the standard of veterinary services in England up to that of Scotland within a reasonable measure of years, because there were not the veterinary surgeons available to provide the whole country with the same intensive inspection as in Scotland.

Mr. WEDDERBURN said it was true that the Milk and Dairies Act began to be applied in Scotland in 1925, whereas in England no similar steps were taken until the passing of the Milk Act in 1934. Therefore for twelve years they had now had a very efficient service in Scotland for the eradication of tuberculosis, which had resulted in there being more attested herds and a smaller proportion of tuberculous cows in non-attested herds in Scotland than in England. There was not the slightest reason why the efficiency of that service should be in any way affected by the centralization. On the contrary, backward areas were more likely to be brought up to the standard of the more progressive authorities in Scotland than they would otherwise be. The Minister was very much alive to the administrative advantages of securing the closest possible connexion between the Scottish veterinary service and Scottish opinion, and to secure this he was prepared to consider the appointment of a separate permanent officer in Edinburgh to keep in touch with the Scottish officers. There would certainly be no reduction in the number of inspections yearly, and there would probably be an increased number of inspections in the minority of counties. If Mr. Stewart's amendment was carried it would involve a separate service for all animal diseases in Edinburgh. The Diseases of Animals Act had been a United Kingdom service for the last forty years. Under that service was administered not only such things as control of sheep scab and foot-and-mouth disease, but also the tuberculosis order in regard to the slaughter of beasts All that was done at present by the Ministry of Agriculture but if they were to have a separate tuberculosis service in Scotland it must involve removing the Diseases of Animals Act administration from the present United Kingdom service to a separate new service in Edinburgh. There were serious objections to that course.

Mr. HENDERSON STEWART asked leave to withdraw his amendment, but the Labour Party opposed this. The amendment was negatived by 210 to 111, and the resolution agreed to.

Pensions of Local Government Officers

The Local Government Superannuation (Scotland) Bill was before a standing committee of the House of Commons on June 29. Mr. NEIL MCLEAN referred to the provision of Clause 35, which allowed the Secretary for Scotland and the Minister of Health to make regulations concerning the rights and liabilities of a person exchanging from employment with a local authority under the English Act for employment with a local authority under the Scottish Act or vice versa.

On the motion that Clause 3 stand part of the Bill Mr. WEDGEWOOD said that Subsection 4 of this clause cut out persons who were subject to the Asylums Officers' Superannuation Act of 1909. He understood that in East Lothian there were individuals who might be cut out of this scheme although there was no other scheme for them at the present time. Dr. ELLIOT said he would do his utmost before the report stage to clear up this point in consultation with the local authorities. The clause was then added to the Bill.

On Clause 5 (Power to admit employees of statutory undertakings and registration officers) Mr. J. F. C. REID, Solicitor-General for Scotland, moved to insert:

> "Where the local authority, being a local authority as defined in the Maternity Services (Scotland) Act, 1937, has made arrangements under Subsection 1 of Section 1 of that Act with a voluntary association for the employment of certified midwives by that association the provisions of Subsection 1 of this section shall apply in relation to statutory undertakers and to employees of those undertakers."

He said that under the recent Maternity Services Act for Scotland there was a provision that a local authority might make arrangements with a voluntary association whereby the necessary midwives in their area were provided by the association. The amendment would give midwives who were engaged through the medium of an association rights similar to those of persons employed by a local authority itself. This applied only to whole-time midwives who were virtually engaged in municipal work. He could not say at the moment whether it would be possible to make with the Queen's nurses the type of arrangement referred to in the Maternity Services Act. The Government would consider the matter. The amendment was accepted, and the clause as amended added to the Bill.

On Clause 6 (Contribution) the committee accepted an amendment proposed by Mr. REID to enable provision for pension rights at the higher rate to be maintained in a case where a man kept the same post but his remuneration was reduced owing to advancing age. The clause as amended was ordered to stand part of the Bill, and after further discussion the committee adjourned until July 1.

On resumption on Clause 16 (Female nurses, midwives, and health visitors) the committee agreed to an amendment proposed by Dr. ELLIOT enabling local authorities to grant compensatory allowances to nurses, midwives, and health visitors although they had not completed forty years' service at 60 years of age. He said the allowance would be an amount not exceeding the difference between the pension to which a person was entitled under the Bill and the pension she might have earned had she continued to serve until she was 65. The clause as amended was agreed to.

On Clause 22 (Modification and replacement of local authorities superannuation scheme) Mr. REID moved an amendment which, he said, would bring into the local acts similar provisions to those which the committee had passed in Clause 3 dealing with contributory employees. The amendment would not deprive anybody of any existing rights and local Acts, and it would safeguard existing practices and provisions affecting authorities which had local Acts. Certain authorities had in operation medical examinations before accepting candidates for office, and the amendment would preserve that practice where it existed. Dr. ELLIOT said the Government would consult the local authorities and draw their specific attention to the amendments that had been made. The committee agreed to the amendment and ordered the clause to stand part of the Bill.

After further amendments Dr. Elliot proposed a new clause dealing with the rights of whole-time officers appointed in a temporary capacity. He said its effect was to secure that in the case of an officer expressly engaged in a temporary capacity for a period of not more than two years a local authority might determine that that officer should not be a contributory employee, but that at the end of two years' local government service, whether continuous or not, such an officer would automatically become a contributory employee whether he remained with the same authority or transferred to another within twelve months.

The clause was approved and added to the Bill.

Drafting amendments were made in the second Schedule (Provisions as to asylum employees), and the Bill as amended was reported to the House.

Government and Cheap Milk

On July 5 the House of Commons in committee considered the financial resolution on which the Bill amending the Milk Acts, 1934 and 1936, will be based. Mr. RAMSBOTHAM, in moving the resolution, said that it regularized the payments of the English Milk Marketing Board to producer-retailers who had taken part in experimental schemes for the supply of cheap milk for nursing and expectant mothers and children under school age in certain parts of the Special Areas. Doubt had arisen whether it was within the legal power of the Board to make these necessary rebates to the producer-retailers, and the resolution would put that beyond doubt.

Mr. JOHNSTON said that the Government was subsidizing milk in schools, and school children were being sold milk at 1s. a gallon. Everybody applauded that, and every medical officer of health, educationist, and nutritionist said that the Government was on the right lines. In the case of children of 4, 3, and 2 years old, babies, the sick and nursing mothers the price was 2s. a gallon. Why should the Government continue to make this difference in the charges? Instead of allowing milk to be diverted to the factories the Government should say to every medical officer of health that as long as a mother with young children cared to go or to send to any authorized distributor of milk she should get it at the same price as that at which it was supplied to the schools.

Mrs. TATE said she had constant complaints from mothers of children at schools that one reason why they did not care for the milk was that it was pasteurized. It was time that there was a real impartial inquiry into the relative nutritive value of pasteurized and unpasteurized milk. The milk-in-schools scheme had been in operation for three or four years, and there should be leaving school a generation of children who had acquired a taste for pasteurized milk. If inquiry were made, however, she thought it would be found that very few children who had left school had continued the milk habit.

Mr. W. S. MORRISON, replying to the debate, said questions had been raised about the pasteurization of milk and other matters which were of great interest to him in attempting to formulate a Government policy on the question of milk. All he asked the committee to do that night was to agree to extend the existing provisions for another twelve months so that he might get some other opportunity of laying before Parliament legislative proposals of a more permanent character.

The resolution was accepted.

On July 6 in the House of Commons the financial resolution on the Milk (Amendment) Bill was agreed to on report, and Mr. RAMSBOTHAM introduced the Bill.

Institutional Treatment of Pulmonary Tuberculosis.—Sir KINGSLEY WOOD told Mr. Messer on June 17 that the numbers of cases of pulmonary tuberculosis treated in public health and approved residential institutions in England and Wales were: 1934, 39,856; 1935, 40,484; 1936, 41,630.

Gas Masks for Civilians.—Up to June 19 9,000,000 gas masks had been made under the Home Office scheme. Mr. LLOYD stated, on June 24, that the United Kingdom had a larger number of gas masks for the civil population than had any other country in the world. The final stage had been reached in preparing the handbook for householders on air raid precautions.

Results of School Medical Inspection at Leicester.—On June 21 Mr. KENNETH LINDSAY, replying to Mr. Lyons, said that during the year ended December 31, 1936, 12,356 school children in the city of Leicester were examined at routine medical inspections and 15,882 at special inspections. There were also 26,257 reinspections. The number of children found at routine medical inspections to require treatment for defects other than defects of nutrition, uncleanliness, and dental diseases was 1,569. Information was not available to show the number of children found to require treatment at special inspections, but 11,277 defects requiring treatment were found. On December 31, 1936, six whole-time medical officers were employed by the local education authority in the work of medical inspection and treatment.

Corporal Punishment in Schools.—Mr. KENNETH LINDSAY, on June 21, informed Mr. Sorensen that the administration of corporal punishment in the schools was a matter which

had always been regarded as within the discretion of the school authorities, and the President of the Board of Education did not see any reason to vary that policy. He was satisfied that during recent years there had been a welcome decrease in the infliction of corporal punishment as a means of maintaining discipline.

Inquiry into the Use of Celluloid.—Mr. CARTLAND, on June 22, asked the Home Secretary whether he had yet set up the departmental committee to inquire into the question of the danger to children and others arising from the use of celluloid toys and other articles, and, if so, what were its terms of reference. Mr. LLOYD replied that Sir Vivian Henderson, formerly Parliamentary Under-Secretary at the Home Office, had consented to act as chairman of this committee, and the Home Secretary hoped that its composition would soon be completed. Its terms of reference would be: "To inquire into the use of celluloid and any similar highly inflammable material in the manufacture of toys, fancy goods, articles of attire, toilet requisites, and the like, and to consider what steps are desirable and practicable against the danger arising to the public, and especially to children, from such use."

Protective Equipment for Mine Workers.—On June 22 Mr. T. SMITH asked to what extent protective equipment in the way of helmets, gloves, etc., was employed in the coalfields. Captain CROOKSHANK said that the reports for 1936 of the divisional inspectors and of the Safety in Mines Research Board, which would shortly be published, showed that satisfactory progress had been made in the coalfields in the use of protective equipment. Hard hats, for example, were bought at a rate of more than 12,000 a month. He wished to express his appreciation of the keenness and co-operation shown by all sections of the industry, which had enabled a gratifying measure of progress to be attained.

New Mental Institution for Surrey.—Mr. BERNAYS informed Mr. De Chair on June 24 that the Surrey County Council proposed to exercise compulsory powers to acquire Merrist Wood Hall, Worplesdon, for a lunatic asylum. A public inquiry would be held at which objections would be heard, and Sir Kingsley Wood would carefully review all the circumstances before coming to a decision.

Scheme of Cheap Milk in the Special Areas.—On June 28 Mr. W. S. MORRISON informed Mr. J. Griffiths that the schemes for the supply of cheap milk in the Special Areas had been inaugurated for experimental purposes by the Milk Marketing Board, with the co-operation of local distributors and of the local authorities concerned, and with financial assistance from the Commissioner for the Special Areas. The Board was of opinion that fuller information on the working of the present schemes was desirable before further action along these lines could be considered.

Practical Dietetics in Schools.—On June 29 Mr. HEPWORTH asked what steps were taken to teach practical dietetics in schools, with special reference to the value of body-building foods. Mr. KENNETH LINDSAY replied that cookery was a regular subject in the education of the older girls in public elementary schools. The curriculum generally included such instruction and training in the principles of proper dieting and their application as were suitable for girls of 12 to 14 years. Some 90 per cent. of all the older girls attending the elementary schools, and rather more than 80 per cent. of those educated in secondary schools, were attending schools in which such instruction was provided.

Medical Examination in Drunkenness Charges.—Answering Sir John Mellor, Sir SAMUEL HOARE said all police forces had instructions that if a prisoner in custody on a charge involving drunkenness desired to be examined by a doctor selected by himself the request was to be complied with on the understanding that the prisoner would be responsible for the doctor's fee.

Notes in Brief

In 1936 the number of certificates of disablement or death from silicosis issued by the Medical Board was 727, including 197 certificates in respect of death.

Medical News

The second World Congress on Mental Hygiene will be held at the Centre Marcelin-Berthelot, Paris, from July 19 to 25. The subjects to be considered include eugenics in the prophylaxis of mental diseases, mental hygiene and sexuality, training at different ages and in various occupational and other environments, administrative and legislative problems; indications for research and propaganda work, and certain psychological aspects. Sir Hubert Bond will propose an international classification of mental affections with respect to nomenclature, Professor D. K. Henderson will open a discussion on the individual and social prophylaxis of suicide, Professor C. I. Meyers will deal with mental hygiene in intellectual work, and Dr. W. M. C. Harrowes will submit a communication on the mental hygiene of the adolescent. Visits have been arranged to mental hospitals near Paris, psychotechnical laboratories, colonies for abnormal children, and Versailles. There will be an exhibition to illustrate the work in various countries in connexion with mental hygiene. Copies of the full programme may be obtained from the secretary of the National Council for Mental Hygiene, 76 and 77, Chandos House, Palmer Street, London, S.W.1.

The sixth International Montessori Congress will be held in Copenhagen under the auspices of the Danish Minister of Education from August 1 to 10. Dr. Maria Montessori will speak on the central subject of the congress, "Educate for Peace," and the opening session will be broadcast. Particulars may be obtained from the General Director, International Montessori Association, 1, Hampstead Hill Gardens, London, N.W.3.

Professor Georges Portmann of Bordeaux and Paris will hold a course in English of practical classes in oto-rhino-laryngology from July 26 to August 29. This will include anatomical demonstrations, various operative procedures, clinical examinations, bronchoscopy, oesophagoscopy, and direct laryngoscopy, with attention to special methods of diagnosis and treatment. Further information may be obtained from Professor Portmann, 15, Rue Franklin, Paris.

The Minister of Health, in accordance with an announcement recently made by him in the House of Commons, has arranged for two officers of his Department, Colonel L. W. Harrison, D.S.O., M.B., and Mr. D. C. L. Ward, accompanied by Dr. Margaret Rorke, director of the venereal diseases department at the Royal Free Hospital, to pay a short visit to Sweden, Norway, Denmark, and Holland for the purpose of studying the systems in operation in those countries for combating venereal diseases. The party left London on July 12, and will be joined later by Dr. T. Ferguson of the Scottish Department of Health.

The issue of *La Presse Médicale* for June 26 is devoted to the International Exhibition in Paris.

The issue of *Le Sud Médical et Chirurgical* for June 15 is devoted to Italian medicine, the contributors being professors from Madeira, Catania, Pisa, Cagliari, and Florence.

The July issue of the *Practitioner* is devoted to the care of the aged, the first article, on "Old Age," being written by Sir Robert Armstrong-Jones.

The Secretary of State for Scotland has appointed Dr. R. P. J. McBroom, senior assistant medical officer at Argyll and Bute Mental Hospital, Lochgilphead, to be a Deputy Commissioner of the General Board of Control for Scotland.

Dr. William Ferriday Jackson has been appointed a Justice of the Peace for the City of Manchester, and Dr. William Edward Houlbrook a Justice of the Peace for the County of Derby.

A new clinic for tropical diseases has been opened in the Policlinic at Naples under the direction of Professor Boeri.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Finance Department, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Finance Department.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCE DEPARTMENT (Advertisements, publishing, subscriptions, etc.) *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Cancrum Oris

Professor G. GREY TURNER, in reply to Dr. Hope Trant (*Journal*, July 3, p. 48) writes: May I say that for many years I have tried practically all methods of treatment, and have been forced to the conclusion that it is best to treat the condition like an acute infective gangrene, and to excise the involved area with the diathermy knife, taking care to cut through the healthy tissues to about a quarter of an inch beyond the spreading edge. Any areas that cannot be excised in this way should be thoroughly treated with the coagulating current. The mutilation involved may be serious, but is no worse than the loss of tissue which is inevitable, and it does hold out a better prospect of recovery than any other form of treatment with which I am familiar.

Vaccines Protecting against Influenza

Dr. CLAUDE A. P. TRUMAN (Exford) writes in reply to Dr. H. V. Mitchell (*Journal*, June 26, p. 1352): A few years ago I had occasion to immunize fifty patients and the staff of an institution against diphtheria. The influenza season was at hand, and a bad epidemic followed shortly. Only two of those inoculated suffered slightly, but the year before they had all succumbed. The same thing happened when the effects of the inoculation had worn off in a year's time. The numbers affected and not affected would appear to rule out coincidence.

Splitting Finger-nails

"A. M. B." writes: I am satisfied that this condition is the result of excessive filing—modern methods of manicure—as opposed to cutting. A blacksmith pares a hoof before using a file.

Income Tax

Assessment of House

"X. X." owns a house valued at £1,500, let at £85 per annum and assessed at £80 gross. He wishes to make alterations costing £400 and to recoup himself by charging additional rent, and inquires as to the effect on the assessment.

*** One result of effecting the alterations will be that the property will come up for reassessment as if it were a different entity—and the fact that it is at present assessed at £80 will not have much, if any, effect. If he increases the rent by, say, 8 per cent. of £400 (to cover interest and sinking fund) the authorities will be entitled to fix the new assessment at £85 + £32 = £117 gross. As against this, however, "X. X." will be entitled to claim against the net assessment the amount of interest paid by him to a building society if the £400 is found in that way. If the tenant signs jointly and pays the £32 to the building society, "X. X." will not receive the allowance, but he will pay more income tax than at present because of the increase in the Schedule A assessment—which will presumably be the same whichever arrangement he made with regard to the interest.

Employment Abroad—Visit to United Kingdom

"EXILE" is employed in the Colonial Medical Service. His wife and son reside in a furnished flat in London, and he remits money to them from abroad. He proposes to come to England in July for six months or so. Will he be liable for income tax, and, if so, would that be affected by restricting the period of his stay in the United Kingdom or making special arrangements with his bank abroad.

*** He will be liable to assessment as for the financial year 1937–8, whether he is here for six months or less. The amount of the gross assessment will be determined by the total amount of income received in, remitted to, or brought to the United Kingdom, but of course he will be entitled to the usual deduction of £180—married personal allowance—and to £60 child relief. The only means of reducing his liaiblity would seem to be by restricting the amount of income received here, for example, by allowing it to accumulate abroad and covering his expenditure here by realizing capital investments; but if he proposes to make some arrangement of that kind legal advice should be taken, as the matter is one of considerable difficulty.

LETTERS, NOTES, ETC.

Coffee and Liquor

H. KOOPMANN and H. KEMPSKI (*Münch. med. Wschr.*, May 14, 1937, p. 780) have carried out a number of investigations on the influence of the consumption of coffee on the concentration of alcohol in blood and urine in persons under the influence of drink. They were able to confirm the well-known sobering influence of coffee, which takes place in spite of the fact that the concentration of the alcohol in the blood remains unchanged. At the same time the alcoholic breath becomes less pronounced, though only temporarily. The concentration of alcohol in the urine increases after the consumption of coffee and eventually becomes greater than the concentration of alcohol in the blood. Therefore, from the medico-legal point of view the concentration of alcohol in the urine is of no significance without a simultaneous examination of the concentration of alcohol in the blood in persons suspected of being under the influence of drink who have partaken of coffee afterwards.

Hairpin in Bladder

Mr. FAUSET WELSH, F.R.C.S., writes: Some years ago I was asked to see a girl of 15 who, out of anatomical curiosity, had inserted a hairpin, three inches long, into her urethra. The hairpin had slipped into the bladder, and was causing her much pain. With an operating cystoscope it was seen to be wedged firmly in the transverse plane in the centre of the bladder. Filling the bladder with fluid did not dislodge it, and the cystoscopic forceps failed to secure a good enough grip to turn the hairpin; nor was this possible when tried through a direct vision straight cystoscope. Ultimately the following manœuvre was successful. A straight pair of urethral forceps were introduced into the bladder through the urethra and the hairpin grasped by the middle. This was accomplished by sense of touch only. A second pair of similar forceps were passed alongside the first pair, and the hairpin grasped nearer to the junction of its two limbs. The first forceps were withdrawn and reintroduced still nearer to the junction, and so on, until the junction was grasped and drawn down easily through the urethra.

Medical Golf

The Irish Medical Golfing Society recently held a meeting, with the following results. The Brady Cup (Mersea Island): R. Lindsay Rea (11), 4 up. Holmes Cup (Moor Park): H. O'N. Butler (18), L. F. Clarke (1), and R. B. Quinn (10) finished level with 75; the first-named won over the second nine holes. Lane Cup: E. T. McElligott (8), who was the winner over the second nine holes, J. L. Walsh (10), and L. F. Clarke (1) were level, 1 down. Scratch Prize: L. F. Clarke, 76. In the Corbett Cup, for those with a handicap of 16 and over, E. F. Kelly and J. Speares tied with 81, the former winning with a better score over the second nine.

We have received from Messrs. George Borwick and Sons, Ltd., a sample of their product Lemon Barley Powder which, dissolved in cold water, makes quite a pleasant summer drink.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

41 Cardiac Psychosis

J. WORTIS (*Amer. Heart J.*, April, 1937, p. 394) believes that true cardiac psychosis occurring in relatively uncomplicated cases of heart failure is uncommon. He was able to find only twenty-six cases in a series of 100 patients suffering from heart failure who were seen by the psychiatric medical service in Bellevue Hospital. It is still impossible to explain the cause of the condition, of which the prognosis is bad. Of nineteen patients whom the author was able to trace sixteen had died within two years, two were seriously ill, and only one was improving. Varying degrees of confusion, especially at night, are found in nearly all cases. In his series Wortis found that 77 per cent. showed clear evidence of anxiety and 89 per cent. had delusions of persecution. The anxiety in some was caused by the knowledge of their serious illness, in others it was due to the presence of delusions or hallucinations, but in the most apprehensive there was no definite reason for anxiety. Wortis believes that when the higher levels of integration are intact the patient is able to provide an apparently reasonable explanation for his anxiety, but when these are disturbed the underlying mood gives rise to unmotivated anxiety. Hallucinations and delusions of all kinds usually occur in cardiac psychosis. In the series of patients 65 per cent. were over-talkative and 46 per cent. circumstantial. The main factor in diagnosis is the association of psychosis with heart failure. Aetiological factors of heart disease, such as syphilis, may independently cause a psychosis. Precordial and cardiac sensations, whatever their origin, may give rise to anxiety states, and, conversely, these sensations are present in all kinds of psychosis. Wortis points out that in cardiac psychosis the psychological mechanism of anxiety may be studied in relation to a circumscribed physical condition, for anxiety may be produced by physical disease and may give rise to persecutory delusions dependent on the degree of associated confusion.

42 Insulin and Vitamin A

M. ROLLER (*Med. Klinik*, May 14, 1937, p. 661) has been able to prove that there is an antagonism between vitamin A and insulin. A greater consumption of vitamin A increases the glycosuria in diabetes. This explains the decreased sensitiveness to insulin following a fat-albuminous diet which is rich in vitamin A and the increased response after a carbohydrate diet which is poor in vitamin A. According to the author, the increased sugar tolerance in hypothyroidism is due to an insufficient conversion of carotin into vitamin A, and he cites a number of clinical observations confirming his thesis.

43 Chromic Acid Poisoning

KRIEGER (*Dtsch. med. Wschr.*, June 1, 1937, p. 893) notes that while chronic chromic acid poisoning is comparatively common, acute poisoning with this acid and its salts is very rare; in 1922 only sixty-two such cases could be collected from the literature, and most of them were caused by potassium bichromate. The author observed a case of attempted suicide by a saddler's apprentice, aged 18, who swallowed a large quantity of potassium bichromate intended for the tanning of leather. He was admitted to hospital fully conscious and showing no signs of collapse. The skin and sclerae were slightly jaundiced, and the lining of his mouth and throat were markedly yellow and slightly oedematous. There was considerable tenderness in the epigastrium with well-defined rigidity of the abdominal muscles. The patient repeatedly vomited very yellow material. This evacuation was supplemented by the stomach pump, and later the patient recovered without any permanent ill effects. What the author regards as a new contribution to the symptomatology of this condition was a positive Babinski's sign, which in this case was clearly demonstrable for four days. Other signs which are, he believes, fairly characteristic are great thirst, tenesmus with loose, cholera-like stools which may or may not contain blood, dyspnoea, cyanosis, coldness of the extremities, pain in the loins, retention of urine, albuminuria, dilatation of the pupils, loss of consciousness, and convulsions. In fatal cases the clinical picture is that of uraemia, and severe gastric haemorrhage may prove fatal. Potassium bichromate is mainly excreted by the urine, and to a lesser extent by the bowels and by the respiratory tract.

Surgery

44 Venous Thrombectomy

A. LÄWEN (*Zbl. Chir.*, April 24, 1937, p. 961) in a man, aged 49, who had been suffering for two days from acute thrombosis of the subclavian and axillary veins incised these vessels and removed the clots. The pain, as well as the arteriospasm which Läwen has frequently found to accompany venous thrombosis, disappeared at once; it was uncertain whether this was due to the restoration of the venous flow or to the interruption of a vein–artery reflex. The latter view is supported by the recent reports of French writers on the quick improvement after resection of large thrombosed veins, and by Leriche's successful treatment of arterial thrombosis, secondary to embolism, by arterial resection. In two cases, both clearly unfavourable, Läwen removed clots, with technical success only, from the femoral and iliac veins. Kulenkampff recently published three cases in which saphenous thrombectomy was attempted with the object of preventing lung infarction and embolus. Läwen does not recommend thrombectomy as a commonly justifiable method of treating venous thrombosis, as the precise anatomical diagnosis is often difficult and the results of conservative treatment are usually satisfactory. He thinks, however, that the operation is worthy of consideration in cases of visible venous clotting, associated with appreciable arteriospasm and perhaps with repeated pulmonary infarctions. Temporary occlusion of the vein by pressure above the thrombus, as a means of preventing the danger of embolus during operation, is preferable to ligature or to leaving the vein open.

45 Injuries of the Semilunar Cartilage

In the experience of H. PRINZ (*Beitr. klin. Chir.*, April 28, 1937, p. 337) these injuries more commonly affect the internal cartilage in the male sex, and are to be diagnosed chiefly from signs of resistance to complete extension and from tenderness between the femur and the tibia when the leg is externally rotated on the thigh with the knee flexed. Each of these symptoms is occasionally absent in spite of a torn cartilage, and each may sometimes be produced in the absence of a tear by the impaction of swollen synovial fringes or by a free foreign body. Steinmann's sign (the shifting—backwards during flexion and forwards during extension of the knee—of the tender point) can sometimes be elicited. The presence or absence of effusion is not important in diagnosis, and a characteristic history is not always obtainable. Ordinary radiography is seldom helpful, but in doubtful cases Böhm's method of radiography after intra-articular injection of 3 to 4 c.cm. of aqueous uroselectan B may be decisive. Endoscopy of the joint is more dangerous than surgical exploration, and is unjustifiable. At

Konjetzny's clinic operation is preferred to conservative treatment for persistent or recurrent derangement. Although the injured and torn parts of the cartilage are removed, its capsular zone's capacity for regeneration is such that it may be left behind when possible, unless the patient is engaged in heavy manual work. Prinz discusses fully the aetiology of the tearing of the semilunar cartilage. In all but three out of fifteen cases microscopical examination showed chronic degenerative or inflammatory changes, which some German and Swiss writers have regarded as primarily causative, trauma playing an unimportant part. Conclusions drawn from histological examination alone, however, are deceptive; it is certain that in a large majority of cases direct or indirect trauma is the chief aetiological factor.

46 Congenital Urethral Atresia

S. R. WOODRUFF and A. H. MILBERT (*Urol. cutan. Rev.*, May, 1937, p. 303) state that congenital atresia of the urethra is one of the rarer anomalies of the urogenital tract. They give references to the literature and record a personal case—that of a male infant who died one hour after birth. After death they found that the left kidney was converted into a thin-walled sac, and the surface of the right kidney was studded with small cysts, the ureters were tortuous and much dilated, and the bladder was uniformly distended. The posterior urethra was represented by a sacculation 3 cm. long and 3 cm. in diameter. In the bulbous urethra there was a diaphragm 2 cm. thick producing the atresia. Besides the urogenital anomaly the child had bilateral talipes varus and a patent foramen ovale and ductus arteriosus Botalli.

47 Fractures of Vertebrae

A. CIMINATA and G. ANDREOLETTI (*Arch. ital. Chir.*, 1937, **45**, 5, p. 505) record forty-six cases of fracture of the vertebral column admitted to the hospital at Monza during the last ten years. The ages of the patients ranged from 15 to 67. The distribution of the lesions and their fatality were as follows: in seventeen cases of lesions in the cervical region there were eleven deaths; in fifteen cases of lesions in the dorsal region there was one death; in fourteen cases of lesions in the lumbar region there were no deaths. Of the eleven deaths in the cervical group four occurred within a few hours and seven within from two to forty-five days with symptoms of paralysis of both upper and lower limbs, paralysis of the sphincters, bedsores, and high temperatures. Of the seven cervical cases which recovered, three had a transient paresis of the limbs and bladder and four showed no symptoms in the limbs or bladder, and had no sequelae. In the dorsal group the single death was preceded by paraplegia, paralyses of the sphincters, bedsores, and high fever; all the others made a complete recovery. In the lumbar cases there were transient parasthesia of the lower limbs and vesical paresis. In only one case was there paraplegia.

Therapeutics

48 Copper in the Economy of Insulin

H. SCHNETZ (*Klin. Wschr.*, May 8, 1937, p. 664) has been able to show that the administration of copper inhibits a blood-sugar rise following the ingestion of 30 grammes of dextrose in healthy persons. Four to eight copper sulphate pills daily were well tolerated. The total quantity of copper in each pill was 2.5 mg., and the daily dosage from 10 to 20 mg. of copper. Schnetz then selected seventeen diabetic cases of varying degrees of severity, noted their daily intake of white bread and their insulin dosage, and began the administration of copper. He found that in severe cases it was possible to decrease the daily insulin dose by 20 to 55 units, in moderate cases by 20 to 45 units, and in mild cases to substitute copper for insulin. In some cases it was possible to increase the daily intake of white bread while decreasing the insulin. The amount of insulin that was saved by the copper depended on the severity of the diabetes, the length of time it had been administered, the individual reaction to copper given orally, and the combination of the copper administered. Schnetz believes that by acting as a catalyst the copper stored in the liver inhibits glycogenolytic stimuli and increases both the ability of the liver to fix glycogen and the formation of glycogen in the liver and muscles. There were no untoward results from the administration of copper, and he found that it produced no resistance to insulin and did no damage to the liver cells. He points out that copper has long been known to have an anti-infectious and anti-anaemic action. The low cost and agreeable method of its adminstration as compared with the unpleasant insulin injections warrant its inclusion in the diabetic armamentarium.

49 Peritoneal Oxygenation in Abdominal Tuberculosis

N. BORDIA (*Indian med. Gaz.*, April, 1937, p. 233) reports good results following oxygenation of the peritoneal cavity in abdominal tuberculosis. Preliminary exploration is performed in doubtful cases; then, under local anaesthesia, a trocar and cannula is introduced through a stab wound an inch below and lateral to the umbilicus. The trocar is removed, an adapter fitted to the cannula, and an initial amount of 200 c.cm. of oxygen allowed to flow in. The patient complains of pain on puncture of the peritoneum. Blockage of the cannula by omentum may be overcome by allowing oxygen to flow in under slightly greater pressure. The operation is repeated at weekly intervals and the quantity of oxygen increased from 350 to 500 c.cm. Pain may be complained of if too large quantities of oxygen are introduced, or if there are adhesions. The temperature usually falls, but may rise if pulmonary tuberculosis is present. A condition resembling dysentery may result from vascular congestion, but it subsides in four or five days when the gas has been absorbed. Surgical emphysema may complicate the operation but is not troublesome. Of 197 cases treated by this method 133 could be followed up. Thirty-four were cured and fifty-eight relieved after six to eight oxygenations, and most of these cases received no other treatment. Bordia concludes by explaining that the probable mode of action is the production of hyperaemia, which helps to combat the disease, and the saturation of the tissues with oxygen, which inhibits the growth of tubercle bacilli. The best results of oxygenation are obtained in early cases, when minute tubercles occur on the peritoneum; in ascitic cases the effect is not well marked. It is helpful in cases of intestinal obstruction due to extensive tuberculous adhesions, and in cases of enlarged tuberculous glands in the abdomen.

Diseases of Children

50 Lymphatic Leukaemia in Childhood

A. CASAUBON and S. COSSOY (*Sem. méd.*, B. Aires, April 29, 1937, p. 1185) record ten cases of lymphatic leukaemia in girls whose ages ranged from 2 to 12 years. All but one of the cases, in which the disease lasted fourteen months, were of the acute type, and its duration was from one to four months. The patients showed enlargement of the peripheral glands, especially those of the neck, axillae, and groins, but in none could the abdominal glands be felt during life. The spleen was always palpable, and the liver was enlarged from one to four fingerbreadths below the costal margin. Haemorrhages in the skin and from the mucous membranes were almost constant. Ulceration of the mucous mem-

branes of the mouth was present in only three cases. Pains of a rheumatic type and in and round the joints occurred in three cases. Fever of varying degree was present in every case, but neither its course nor its duration was characteristic. In only four cases was the number of leucocytes considerable—namely, 300,000, 108,800, 48,000, and 30,600. The greatest increase in the differential count occurred among the lymphocytes, which in one case formed 65 per cent. of the total white count, while the polymorphonuclears reached very low levels. The number of red corpuscles was always diminished, the lowest recorded being 640,000 with 10 per cent. haemoglobin. Blood platelets were counted in four cases and found normal in one and diminished in three. In treatment only transient improvement followed radiotherapy or blood transfusion.

51 Juvenile Delinquents

R. G. GORDON (*Arch. Dis. Childh.*, April, 1937, p. 111) draws attention to the fact that delinquency is often due to the broken home, and several cases are described in support of this view. Where the home is too unsatisfactory for the child to remain in it the Public Assistance Committee may send him to one of their cottage homes or to foster parents. When this is done at an early age the result is good, but at a later age it is not so successful. Few foster parents of the right kind are willing to take an older child who has already been in trouble. Some of these delinquent children go to residential schools, training ships, etc., where they often do well, but there are not nearly enough of these institutions to take them all. With regard to the residential schools, the ordinary entrance is through the courts; either the child must be charged with a crime or the parents must come to the courts complaining that their child is out of control. Most parents are too indifferent to do this, or they feel that it reflects badly on themselves. Moreover, magistrates are quite rightly chary of relieving a bad parent of responsibility towards his child and of putting the cost on the taxpayer. Most children do not come before the court until they have done something really bad, and even so many magistrates regard it as a first offence and put them on probation. Under proper conditions this is an excellent system, but when no co-operation can be expected from the parents it is useless.

52 Streptococcal Meningitis

J. P. SCOTT and S. X. RADBILL (*J. Pediat.*, April, 1937, p. 486), who record an illustrative case, remark that while streptococcal meningitis is a fairly common disease only a few recoveries are reported annually. In a series of 284 cases of meningitis at the Philadelphia Children's Hospital thirty-two (11 per cent.) were due to streptococci, and none of these recovered. The writer's case was that of a girl aged 6, in whom *Streptococcus haemolyticus* meningitis was apparently secondary to a severe infection of the upper respiratory tract with otitis and mastoiditis. In addition, mastoidectomy was done, and convalescent scarlet fever serum administered intraspinally may have helped the process of recovery. The patient had in all eight spinal punctures, one intravenous injection of glucose, and five whole blood transfusions. She was given intrathecally three injections, each of 30 c.cm., of convalescent scarlet fever serum, and one injection of 30 c.cm. of the same serum intramuscularly. She also had one injection intrathecally of 30 c.cm. of pooled adult serum, as no scarlet fever serum was available that day. E. D. ANDERSON (*J. Amer. med. Ass.*, May 8, 1937, p. 1591), who also records an illustrative case, states that Caussé, Loiseau, and Gisselbrecht made the first report in the literature of a case of haemolytic streptococcus meningitis with recovery after treatment with prontosil. The conclusions of all the authors appear to be that prontosil is of value in the treatment of haemolytic streptococcus infection, but has little or no effect on other strains or other organisms. Anderson's case was that of a boy aged 9, who developed otogenic haemolytic streptococcus meningitis. Recovery took place under treatment by prontosil, of which 5 c.cm. of a 2.5 per cent. solution was given intramuscularly twice daily, with two 0.3 gramme tablets of sulphanilamide three times daily by mouth. Seven doses of prontosil were given and the sulphanilamide was administered for six days. Rapid and complete recovery took place.

53 Acute Suprarenal Insufficiency

J. W. CAMERER (*Jhrb. Kinderheilk.*, April, 1937, p. 66) who records an illustrative case, states that the occurrence of acute suprarenal insufficiency as the cause of death in infectious diseases has received little attention in German paediatric literature. The symptoms are adynamia, prostration, obstinate vomiting, diarrhoea, and a fall of blood pressure. The diagnosis is confirmed by sudden aggravation of the condition and the appearance of pigmentation. Camerer's patient was a boy aged 3, who three weeks after a mild attack of scarlet fever developed symptoms of acute suprarenal insufficiency. He died in less than two months in spite of the administration of various preparations of suprarenal extract and of vitamin C. The necropsy showed extensive necrosis of all the layers of the suprarenal cortex and slight involvement of the medulla.

54 Pulmonary Tuberculosis

F. MATTHÄUS (*Dtsch. Tuber.-bl.*, June, 1937, p. 146) conducted in 1936 a follow-up study of 150 children who, in the period 1921–32 were treated at a tuberculosis hospital for children at Scheidegg-Allgäu. All gave positive reactions to cutaneous or intracutaneous tuberculin tests, and all showed radiological signs of infiltration of the lungs, the right lung being involved in 60 per cent., the left in 40 per cent. In fifty cases there had been intimate contact with cases of tuberculosis, in seventeen cases the children suffered from some form or other of surgical tuberculosis, and fifteen of them were scrofulous. In eighty-three cases coughing was noted, and the temperature was quite high in two cases and subfebrile for a considerable time in thirty-one. In 117 cases the children were continuously afebrile except for brief bouts of fever due to intercurrent infections. In 113 cases physical signs were demonstrable in the lungs, but were not well marked. The duration of hospital treatment in most of these cases was from three to four months, but the treatment of the children with surgical tuberculosis lasted from twelve to eighteen months. There were only two deaths, one from diphtheria and one from measles complicated by bronchopneumonia. The follow-up study of the surviving 148 revealed that all were well, although several were subject to frequent attacks of tonsillitis and catarrh of the upper respiratory tract. This catarrhal predisposition is, in the author's opinion, common in all children at puberty.

55 Persistent Vernix Caseosa and Exudative Diathesis

E. MAYERHOFER *et al.* (*Wien. klin. Wschr.*, May 28, 1937, p. 841) state that in the newborn there is a definite relation between persistent vernix caseosa and the exudative diathesis. Usually during the second month of life symmetrical patches below the knees are noticed which are due to incrustations of dirt on persistent remains of vernix on the subpatellar skin ridges. These patches have been noted as early as the fourteenth day of life and as late as the seventh month, and they may occur on any part of the body. Mayerhofer noted the condition in 16 per cent. of 461 newborn children. He and his coworkers found that the exudative diathesis coexisted in eighty-five of 120 children with persistent vernix caseosa. It manifested itself in various eczematous forms, in inter-

trigo, lichen, seborrhoea capitis, marked presence of lanugo hairs, lingua geographica, and in some cases in severe asthmatic attacks. The persistence of vernix caseosa is thought to be due to an endogenous constitutional factor and an exogenous hormonal factor. Its presence is the earliest and most important indication of a possible later development of the exudative diathesis.

Obstetrics and Gynaecology

56 Pregnancy and Parkinsonism

T. LUSTRA, R. C. BIZZOZERO, and P. A. ALEGRE (*Ann. bras. Gynec.*, May, 1937, p. 373), who record an illustrative case, state that the association of pregnancy and post-encephalitic Parkinsonism is very uncommon. Their patient, who had given birth to seven children, was aged 38, and had suffered eight years previously from some undiagnosed febrile disease during the fifth month of her fourth pregnancy. After this confinement she presented tremors of the left leg, which afterwards spread to both arms. Subsequently her expression became fixed and her movements slow and difficult. The fifth pregnancy, during which a diagnosis of post-encephalitic Parkinsonism was made, ended in a normal confinement, and the baby was normal; the next two pregnancies were also uneventful and the children were normal. According to the literature, at least 75 per cent. of the cases of acute encephalitis in pregnancy develop symptoms of Parkinsonism, and most authors maintain that it does not have any ill effect on the pregnancy. The frequency of abortion or premature labour is no higher than usual. Conversely, opinions differ as to the effect of pregnancy or childbirth on Parkinsonism; many writers say that the nervous condition is not affected. Roques, on the other hand, reported thirty-four cases in which Parkinsonism was aggravated or first appeared during pregnancy. In twenty-one cases the onset or aggravation of this disease occurred at an early stage, and in fourteen cases early in the puerperium. Transmission of nervous disease to the child appears to be exceedingly rare.

57 Tocography

S. LÓRÁND (*Zbl. Gynäk.*, May 29, 1937, p. 1285) has analysed tocographically the uterine and abdominal contractions during labour. He distinguishes the following types of labour pains: the pains of the normal uterus, the optimal labour pains, and the pains met with in primary weakness of the uterus. This last is subdivided into hypotonic, normotonic, and hypertonic or spastic. There is also the weakness caused by deficient abdominal contractions, a hypotonic type with contractions stronger than the normal, and a hypertonic type with contractions of the average strength. The early recognition of these variations in contractions allows a rational individual management of labour in pathological cases.

58 Granulosa Cell Tumours

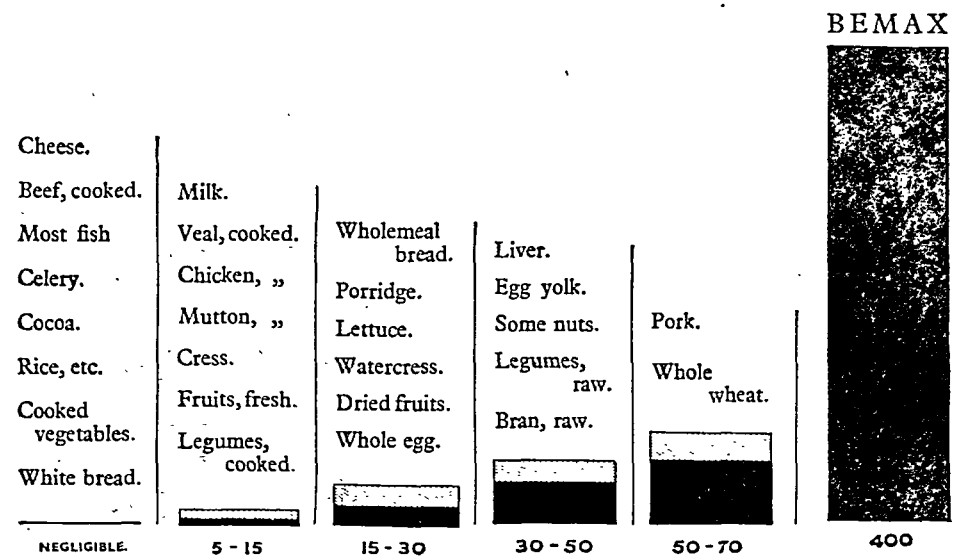
J. V. MEIGS and L. PARSONS (*New Engl. J. Med.*, April 22, 1937, p. 681) describe several granulosa cell tumours of the ovary and suggest that they are not uncommon. There are various cell structures in the tumour, and the authors distinguish three types—the granulosa cell type, the luteoma, and the "thecoma." The clinical diagnosis is confirmed by amenorrhoea or menorrhagia, high content of oestrin in the urine, and by an endometrium of the oestrin phase. The presence of the tumour is also suggested by precocious genital development and the early onset of menstruation. Benign tumours of the breast in women of all ages are also suggestive of this condition. The tumours are usually benign, but may also be malignant. In older women radical surgical operation is the treatment of choice.

Pathology

59 Tubero-infundibular Diabetes

M. KAHANE (*Rif. med.*, April 24, 1937, p. 606) records his experiments on ten white rats to determine the existence of a tubero-infundibular diabetes. The glycaemia was estimated by the Bang-Weiss method and the hepatic glycogen by a modification of Bierry's method. Punctures of the infundibulum were made with the thermocautery through the palate and the infundibular region was examined post mortem. Hyperglycaemia began immediately after the puncture and showed its highest increase in three hours, returning to normal or subnormal in twenty-four hours, while the hepatic glycogen showed a progressive diminution.

60 Corpus Luteum Hormone



K. EHRHARDT and E. HARDT (*Med. Welt*, May 29, 1937, p. 745) have investigated human and animal placentae for the presence of corpus luteum hormone, and have come to the following conclusions. The hormone is present in human placenta between the fifth and the eighth months of pregnancy. It was found in two out of six cases in extracts of horse placenta, and in all cases of goat placenta, but was absent in cow, sheep, and dog placenta. Its presence could not be demonstrated in the foetal organs, but slight traces were found in the foetal urine. A large quantity was found in an extract of a hydatid mole. The administration of this hormone to pregnant mice caused intra-uterine death of the foetuses. It should, therefore, not be given indiscriminately to pregnant women.

61 Addition of Vitamins to Butter and Margarine

H. MÖLLGAARD (*Ugeskr. Laeg.*, June 3, 1937, p. 604), who acts in an advisory capacity to the dairy industry in Denmark, states that recent investigations have shown that a surprisingly large proportion of the community suffer from more or less latent vitamin A deficiency, and that the vitamin A content of winter butter is comparatively low. If the dairy industry goes on ignoring this state of affairs, and if cattle continue to be fed to a large extent on oil cake in winter, the time will come when Danish butter may find a dangerous competitor in margarine to which vitamins have been added. In Professor Möllgaard's opinion the farmer should meet the eventuality of margarine containing more vitamins than winter butter by increasing the winter supply of preserved, protein-rich green fodder. The realization during the past two years of this principle in certain quarters has not, however, brought up the vitamin A content of winter butter to the level margarine will soon attain in this respect, and during the past year investigations have been conducted in connexion with the extraction of carotin, a source of vitamin A, from lucerne. One product of these investigations has been an oily solution of which the vitamin A content is between 4,500 and 5,000 international units per gramme, from 66 to 70 per cent. of its colouring matter consisting of β-carotin. This carotin oil is not costly to produce, and it can be added to butter in such quantities that its vitamin A content is raised by about 10,000 units per kilo without the properties of the butter being altered in other respects. Similar tests have been carried out with margarine, and the stability of carotin oil in butter and margarine has also been investigated. As the comparatively high vitamin A content of Danish summer butter mainly depends on its carotinin content, the addition of carotin to butter as a colouring agent and to raise its vitamin A content must be considered as quite rational. Professor Möllgaard is still diffident about artificially raising the vitamin D content of margarine, for he considers that the chemistry of cholesterin is still so imperfectly understood that it would be unwise to take liberties with it in this respect.

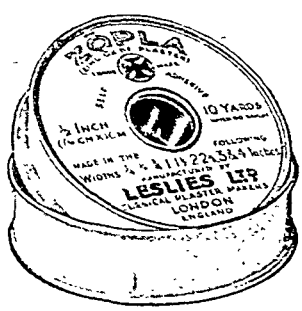
MODERN AIDS TO HEARING

These announcements are intended to illustrate the latest advances in acoustic science in order that the medical profession may be kept informed of the newest aids available for the deaf.

"Electro-Ear"



Bone conduction micro-telephone wearable aid sometimes suitable for cases of catarrhal deafness, otosclerosis and ankylosis. The instrument comprises the transmitter, amplifier on battery, and bone conduction oscillator, held to the head by a light headband. These aids are easily worn inconspicuously and are very effective for conversation, particularly at reasonably short distances.

A copy of our new booklet describing all types of aids will gladly be sent on request.

The service with facilities for testing and comparing almost every make of aid, with individual assistance in each case.

"CERABAN" ADHESIVE SELF-SUPPORTING BANDAGE

The Supplementary or Alternative Treatment to Self-Adhesive Elastic Bandages for
SPRAINS, DISLOCATIONS, CONTUSIONS, SWELLINGS, VARICOSE VEINS, VARICOSE ULCERS, etc.

Its use eliminates the risk of Dermatitis which so frequently arises from the application of Self-adhesive Bandages.

"CERABAN" whilst free from rubber, possesses elastic properties and when carefully applied to the limb gives substantial support. It is porous, adhesive, and non-irritating, will not chafe and permits of complete respiration of the skin.

In the treatment of Varicose Ulcers the use of "Ceraban" Bandage eliminates the risk of Dermatitis which occasionally occurs through the application of self-adhesive Elastic Bandages. In the less severe of such cases a distinguished authority writing in the *Lancet, page 580, Sept. 7th, 1935, issue* recommends the use of "Ceraban" Bandage cut in strips as a first and protective dressing prior to covering with self-adhesive Elastic Bandage and in the more serious cases the complete replacement by "Ceraban." It is waterproof, antiseptic, and being spread on an extensible material readily conforms to the shape of the limb and therefore will not slip.

INVESTMENT TRUST UNITS

¶ After any period of depression investment trust companies are among the last to reflect recovery. While shareholders in the majority of industrial companies have already enjoyed the 1934-35 recovery in the shape of higher dividends, shareholders in investment trust companies, owing to the 'time-lag' factor, have only recently started to benefit.

¶ Units may be purchased and full particulars obtained through any Stockbroker or Bank.

The Managers of Investment Trust Units estimate an initial gross yield based on cash dividends, after allowing for management charges, of not less than 4 per cent. Lloyds Bank Limited are Custodian Trustees of the underlying securities of Investment Trust Units, they collect the dividends on the underlying securities and distribute the income to Unit holders. Price of Units, 13th July, 17s. 6d.

TREFRIW (SULPHUR-IRON) WELLS

THE SPA OF OUTSTANDING MERIT

1. These unique waters are of exceptional merit. With other properties they contain Iron as FERROUS-SULPHATE, and in such concentration that the maximum prescribed dose is only ONE OUNCE.
2. Wonderfully efficacious for all forms of rheumatic disease. Many very remarkable results are obtained in severe and chronic rheumatism and rheumatoid-arthritis—even bedridden cases of long standing—from the home treatment alone.
3. A most important feature of this Spa is the bottling of the waters in natural Spa condition for the

SPA CURE AT HOME

Particulars and specimen of the bottled waters post free from THE SPA DIRECTOR, TREFRIW WELLS, TREFRIW, N. WALES, the only address from which the waters are obtainable.

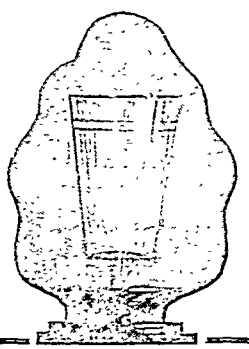
Choose a Spa in Czechoslovakia . . .

The Spas and Health Resorts of Czechoslovakia, with their centuries-old tradition of healing, reinforced by the experience and researches of local specialists, invite your serious consideration.



In addition to places of world-wide repute such as:

PISTANY (Piestany) **CARLSBAD** (Karlovy Vary) **MARIENBAD** (Marianské Lázne) **FRANZENSBAD** (Frantiskovy Lázne)

ST. JOACHIMSTHAL (Jachymov) **TEPLICE-SANOV** (Teplitz-Schönau) **LUHACOVICE** **SLIAC** **TRENCIANSKE-TEPLICE**

with their medicinal springs and mud baths, there are numerous smaller spas and health resorts admirably equipped for the treatment of many diseases, including those in the following groups:

ANAEMIA AND CHLOROSIS.
BASEDOW'S DISEASE.
BRONCHIAL CATARRH.
CONSTITUTIONAL DISEASES. SCROFULA, RICKETS.
DIGESTIVE DISEASES.
DISEASES OF THE BLADDER AND URINARY ORGANS.
DISEASES OF THE KIDNEYS.
DISEASES OF THE NOSE AND THROAT.
DISEASES OF WOMEN.
DISORDERS OF BONES, MUSCLES, AND JOINTS.
DISORDERS OF THE HEART.
DISORDERS OF METABOLISM AND GOUT.
GALLSTONES.
LEUCAEMIA.
NERVOUS DISEASES AND POST HEMIPLEGIC CONDITIONS.
TUBERCULOSIS OF THE LUNGS

The arrangements in the bath establishments are up-to-date in every way, the cleanliness and neatness proverbial, the service attentive and courteous.

It is accepted that a spa cure to be fully beneficial should provide a complete change of surroundings, and a break with the patient's normal everyday life.

The Czechoslovak Spas fulfil this purpose admirably . . . comfortable hotels . . . first-class orchestras and dance bands . . . every facility for sport—tennis, golf, swimming, riding fishing, etc.

There are also numerous fully up-to-date homes for convalescence and rest cures.

For travel information, descriptive brochure, etc., apply to:

THOS. COOK & SON LTD., BERKELEY STREET, LONDON, W.1,
OR ANY OF THEIR 350 BRANCHES THROUGHOUT THE WORLD.

UNIVERSITY OF CAMBRIDGE

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY

The next course of study for the Diploma begins about October 5th, 1937, and occupies about nine months. It comprises:

(a) Four months' instruction in Physics, Radiology, and Pathology.
(b) Three months' further instruction in Radiology and Electrology, together with three months' clinical work in the Radiological Department of a Hospital approved by the Managing Committee for the Diploma.
(c) Two months' experience as clinical assistant in the Radiological Department of a Hospital approved by the Committee. Hospitals in London, in the Provinces, and Overseas have been approved for this part of the Course.

Examinations for Part I (Physics) will be held in February and July, 1938, and for Part II (Radiology, Electrology, and Pathology) in July and October, 1938.

The University has decided that the Diploma shal cease to be granted after 1941. The last course for the Diploma will start in October, 1940, and the last examination will be held in October, 1941.

The Courses are open to men and women whose medical qualifications are approved by the General Medical Council for purposes of registration, and who satisfy the Committee that they have had sufficient post-graduate clinical experience.

Further information about the Courses may be obtained from:
G. STEAD, M.A., Secretary for the Diploma, Cavendish Laboratory, Cambridge,
or THE GENERAL SECRETARY,
British Institute of Radiology, 32, Welbeck Street, London, W.1.

UNIVERSITY OF DUBLIN

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

Applications are invited for the post of RESIDENT ANAESTHETIST AND EMERGENCY OFFICER (male). The appointment will be for three months. Salary at the rate of £130 per annum, with board, residence and laundry. Candidates, who must be unmarried and duly registered, are requested to forward their applications, stating age, qualifications, etc., together with copies of not more than four recent testimonials, to the undersigned as soon as possible.

J. A. BEARDSALL,
July 12th, 1937. Secretary-Superintendent.

THE ROYAL SOCIETY.

Foulerton Research Fellowships.

Applications are invited by the Council of the Royal Society for two FOULERTON RESEARCH FELLOWSHIPS IN MEDICINE, tenable in any Hospital or Medical School in the British Isles. Candidates, who must be of British nationality and British parentage, should supply the usual personal details and give the names of TWO referees. Testimonials will not be considered. Applicants and referees at a distance may write direct to the address given below, without first obtaining forms. The subject of the proposed research, and the place at which it would be carried out, together with the name of the Head of the Department should be given.

The appointment will be for two years in the first instance, from January 1st, 1938, and may be renewed annually up to a total of five years. It will be subject to the conditions governing Royal Society Research Appointments. The stipends will be £600–£800 per annum, with superannuation benefits.

Applications should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W.1, and should be received as early as possible, in any case not later than Saturday, October 16th, 1937.

ROYAL NAVAL DENTAL SERVICE.

The Establishment of DENTAL OFFICERS in the Royal Navy has been increased, and applications are invited for EIGHT APPOINTMENTS to be filled in October next. Further appointments will be offered later.

Candidates must be British subjects of pure European descent and sons of persons who are British subjects. They must be under the age of 28 years on the date of entry, possess the degree or diploma of a British University or College of Surgeons, registered under the Dentists' Act in force in the United Kingdom, and physically fit for service in any climate. Unmarried candidates will be preferred.

Approved candidates will be required to present themselves at the Admiralty for physical examination by a Board of Naval Medical Officers and interview by a Selection Committee, and if selected for appointment will be given a Short Service Commission for six years. At the end of this period they will retire with a gratuity of £1,000 unless during the fifth year of service they have applied for, and have been accepted for, transfer to a Permanent Commission.

Candidates who have, since qualifying, held full time appointments as House Surgeons at Dental Hospitals and Schools will be eligible for an antedate of seniority up to a maximum of *six months*

Application forms and a pamphlet showing the regulations for entry and outlining the conditions of service, rates of pay and allowances, etc., may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1.

Applications for entry in October must reach the Admiralty not later than September 1st.

UNIVERSITY OF LONDON

The Senate invite applications for the UNIVERSITY READERSHIP IN BACTERIOLOGY, tenable at the British Postgraduate Medical School. Initial salary £800 a year. Applications (12 copies) must be received not later than first post on September 15th, 1937, by the Academic Registrar, University of London, W.C.1, from whom further particulars should be obtained.

THE AUCKLAND HOSPITAL BOARD.

A DEPUTY MEDICAL SUPERINTENDENT is required for the General Hospital at Auckland, New Zealand. Particulars of appointment and form of application are obtainable at the Office of the High Commissioner for New Zealand, 415, Strand, London, W.C.2.

Auckland, New Zealand. H. A. SOMMERVILLE, Secretary.
June 3rd, 1937.

THE POLYTECHNIC, REGENT STREET, W.1.

LECTURESHIP IN HUMAN EMBRYOLOGY AND HISTOLOGY.

The University Court invite applications for the vacant Lectureship in Human Embryology and Histology in the Department of Anatomy. Initial salary £500 to £600 per annum (subject to superannuation provision) according to experience and qualifications. Applications (five copies), which should give particulars of training and experience and the names of referees acquainted with the candidate's work, should reach the undersigned not later than August 6th, 1937. Further particulars will be sent on request.

J. S. MUIRHEAD,
July, 1937 Secretary of University Court.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

ASSISTANT IN THE DEPARTMENT OF MORBID ANATOMY.

Applications are invited for the appointment of Assistant in the Department of Morbid Anatomy at University College Hospital Medical School, commencing in the month of September, 1937.

Salary £250 per annum, with superannuation benefits and emoluments.

Applications should be addressed to the Dean of the Medical School, University Street, W.C.1, and must be received on or before July 30th, 1937.

BOARD OF EDUCATION.

The Board of Education invite applications for appointment to a new post of DIETICIAN or NUTRITIONIST early in 1938. The selected candidate will be employed as inspector of the arrangements made by Local Education Authorities for the provision of meals. Applicants must possess qualifications in Domestic Science and experience in cooking. Knowledge of physiology, training in *dietetics, experience in catering for large numbers* and in social work would be additional qualifications.

The scale of salary is £500—£25—£800. A higher minimum salary may be paid in exceptional circumstances.

Further particulars, together with the application form, which must be returned completed not later than Saturday, August 7th, 1937, may be obtained on application in writing to the Secretary, Board of Education, Whitehall, London, S.W.1.

THE KIDDERMINSTER AND DISTRICT GENERAL HOSPITAL.

JUNIOR HOUSE SURGEON (Male) required. Salary £100 per annum, with residence, board and laundry. Applications, with not more than three testimonials, to be sent to the Secretary, Miss Susan Smith, South Cliff, Kidderminster.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE

The Secretary of State for the Colonies proposes to select within the next few months not less than five Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa or in Malaya.

QUALIFICATIONS. Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY. Initial salaries vary from £600 to £700 and rise by increments to a maximum of between £1000 and £1200.

PRIVATE PRACTICE. Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS. In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES. Free first-class passages are provided, on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.

TERMS OF APPOINTMENT. The appointments are pensionable, subject to a probationary period which varies from two to three years.

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE. Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas.

DUTIES. Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery, in public health and in medical research.

Further particulars and forms of application may be obtained from the **Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S.W. 1.**

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

CITY OF BIRMINGHAM.

PUBLIC HEALTH DEPARTMENT.

DUDLEY ROAD HOSPITAL (920 Beds).

ASSISTANT PATHOLOGIST.

Applications are invited for the post of Assistant Pathologist at Dudley Road Hospital, at a salary of £650 per annum, rising by annual increments of £50 to £800 per annum.

Applicants must have special knowledge and experience in morbid anatomy and bacteriology and be engaged wholly or chiefly in the practice of Pathology. The officer appointed will work under the Pathologist to the Municipal Hospitals.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

The successful candidate will be required to pass an approved medical examination, to contribute to the Superannuation Scheme established under the Local Government and Other Officers' Superannuation Act, 1922, as amended by Section 82 of the Birmingham Corporation Act, 1935 (Annuities for Widows), and, if under 30 years of age, to join the Birmingham Municipal Officers' Widows' and Orphans' Pensions Scheme.

The appointment will be terminable by one month's notice on either side.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be addressed to Dr. F. W. Ellis, Medical Superintendent, Dudley Road Hospital, Birmingham, 18, not later than July 24th, 1937, from whom further particulars regarding the post can be obtained.

F. H. C. WILTSHIRE.
The Council House, Town Clerk.
Birmingham, 1.

CITY OF BIRMINGHAM.

ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

The Public Health Committee invite applications from Medical Officers (women) to take charge of Toddlers' Clinics in connection with the Maternity and Child Welfare Scheme. Applicants must have held a six-months' appointment as Physician in a Children's Hospital, and also held a six-months' resident appointment in a Maternity Hospital. It is desirable that applicants should hold the Diploma in Public Health, and if they have not already obtained the Master of Midwifery Diploma they may be required to do so within a subsequent period. The salary will be £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum. The appointment will be subject to the Birmingham Corporation Superannuation Scheme and to the candidate passing a medical examination, and will be subject to three months' notice on either side.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by her.

Applications, endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, to be made on a form obtainable from the Medical Officer of Health, Council House, Birmingham, 3, and returned to him on or before July 24th, 1937.

BRIDGEND URBAN AND PENYBONT RURAL DISTRICT COUNCILS.

JOINT APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH FOR MATERNITY AND CHILD WELFARE.

The above Councils invite applications from fully qualified medical men or women for the post of whole-time Assistant Medical Officer for Maternity and Child Welfare work.

Candidates should have had three years' (at least) experience in the practice of their profession and special experience in

(a) Child Welfare
(b) Ante-natal work,

subsequent to qualification.

It is desirable that candidates should have—
(1) had experience in general practice;
(2) a diploma in Public Health.

The salary will be at the rate of £500 per annum, rising by increments of £25 per annum to £700 per annum. Two-thirds of the salary will be subject to a deduction of 5 per cent. in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922. Travelling expenses in the Penybont area will be paid by the Penybont Rural District Council.

The person appointed will be required to give his or her whole time to the work, and must not engage in general practice.

The appointment will be determinable by three months' notice on either side.

Applications, on forms to be obtained from me at the address below, are to be received by me at the same address not later than 10 a.m. on Monday, July 19th, 1937.

By Order,
Penybont Offices, W. E. BEVAN,
Coity Road, Clerk to the Penybont
Bridgend, Glam. Council.
July 5th, 1937.

CITY OF PORTSMOUTH.

ST. MARY'S HOSPITAL.

The Portsmouth City Council invite applications for the appointment of SENIOR RESIDENT MEDICAL OFFICER for Saint Mary's Hospital, Maternity Department. The appointment includes service at any institution belonging to the City Council that may be required and will be limited to a term not exceeding two years. Salary for the first year £350 and for the second year £375. The residential emoluments are valued at £125 per annum, and the appointment will be subject to one month's notice on either side.

Candidates must be single gentlemen, duly registered, and age 25 to 30 years, and must have had at least one year's experience in a Maternity Hospital.

The Department has at present about 800 births per annum and an Ante-natal and Post-natal clinic is conducted in connection therewith. There is a Resident Medical Superintendent at the Hospital and a Consultant Obstetrician attends regularly and is on call for emergencies.

The appointment is one of value to a medical man specialising in obstetrics who desires to take the M.M., or M.C.O.G., Diplomas.

Application forms, giving conditions of appointment, may be obtained from, and should be returned to, the undersigned, Guildhall, Portsmouth, on or before 10 a.m. on Tuesday, July 27th, 1937.

Canvassing will be a disqualification.
The Guildhall, F. J. SPARKS.
Portsmouth, Town Clerk.
July 6th, 1937.

CITY AND COUNTY OF BRISTOL.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council invite applications for a whole-time male Assistant Medical Officer of Health. Age not exceeding 40 years. Salary £500 per annum, rising by annual increments of £50 to £700. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. The Diploma of Public Health is essential.

The duties will consist principally of examination of children in the Council's Secondary, Elementary and Special Schools, treatment in School Clinics, etc., but the officer appointed may also be required to work in any department of the Medical Officer of Health of the City and Port. He will especially be required to take his duty in rotation at the Port.

Applications, which must be on the form provided for this purpose, should be accompanied by not more than three recent testimonials, and must be received by the undersigned not later than Friday, July 23rd, 1937. Envelopes should be endorsed "Assistant Medical Officer of Health."

Canvassing will disqualify.
Council House, JOSIAH GREEN,
Bristol, 1. Town Clerk
July 5th, 1937.

LINCOLNSHIRE (KESTEVEN) COUNTY COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from qualified medical men for the post of Assistant Medical Officer of Health.

The Officer appointed will be required to act as Assistant Tuberculosis Officer and School Medical Officer, and to undertake Maternity and Child Welfare Work, and such other duties as may be assigned to him.

The salary will be £500 per annum, rising by annual increments of £25 to £700, together with travelling allowance in accordance with the County Scale. Approved previous experience will be taken into consideration.

The appointment, which will be terminable by three months' notice on either side, will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass the necessary medical examination.

Applications should be made on forms which may be obtained from the undersigned and must reach him not later than July 23rd, 1937.

Canvassing in any form will be a disqualification
County Offices, W. T PHIPPS,
Sleaford, Lincs. Clerk of the County Council.

GENERAL INFIRMARY, SALISBURY.

(Voluntary Hospital, 191 beds, now in course of extension to 225 beds.)

RESIDENT MEDICAL OFFICER (male)

required to commence duty as soon as possible.

The appointment is for one year, including a three months' probationary period, with the option of extension.

Candidates must have held at least one appointment at a recognised hospital as House Physician and/or House Surgeon and Anaesthetist, either separately or in conjunction with the former.

He must reside in the Infirmary and devote his whole time to the service of the Infirmary.

Salary £250 per annum, with board-residence.

Applications, with copies of testimonials, to be sent to the House Governor and Secretary.

COUNTY BOROUGH OF OLDHAM.

THE MUNICIPAL HOSPITAL.

RESIDENT SURGICAL OFFICER.

Applications are invited from fully qualified Medical Practitioners for the position of Resident Surgical Officer at the Municipal Hospital.

The appointed candidate will work under the direction of the Medical Superintendent and the Visiting Surgeons.

The duties are mainly surgical (general and emergency), and preference will be given to candidates possessing the F.R.C.S. or other higher surgical qualifications and previous surgical experience.

The appointed candidate will deputise for the Medical Superintendent when required, and undertake such duties as the Council may direct.

He must devote his whole time to the duties of the office, and will not be allowed to engage in private practice.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to £550, together with board-residence and laundry. All fees and emoluments of every kind whatsoever must be handed over to the Corporation.

The appointment is for a period of two years, and is terminable by two months' notice on either side. It is also subject to the passing of a satisfactory medical examination.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be forwarded to the Medical Officer of Health, Town Hall, Oldham, and endorsed "Resident Surgical Officer," so as to reach him not later than July 26th, 1937.

Canvassing in any form will be a disqualification.
JOSEPH J. WILLIAMS, LL.D.
Town Hall, Town Clerk.
Oldham.
July 5th, 1937.

AMENDED ADVERTISEMENT.

CITY OF PLYMOUTH.

CITY GENERAL HOSPITAL (570 Beds).

DEPUTY MEDICAL SUPERINTENDENT.

Applications are invited from fully qualified male Medical Practitioners for the post of Deputy Medical Superintendent at the City Hospital, Plymouth. The appointed candidate will work under the direction of the Medical Superintendent. The duties are mainly medical and candidates should have had medical experience, and preference will be given to candidates possessing a higher medical qualification.

Salary at the rate of £450 per annum, rising by annual increments of £50 to £550, with full residential emoluments.

The appointment will be held during the pleasure of the Council and will be subject to:

(1) The candidate passing a medical examination.
(2) To the provisions of the Local Government and Other Officers' Superannuation Act.
(3) Six weeks' notice on either side.

The officer will be required to refund to the Council all fees, allowances and emoluments other than the foregoing received by him.

Further particulars of the post may be obtained from the Medical Superintendent, City Hospital, Plymouth. Forms of application may be obtained from the undersigned, and should be returned, accompanied by copies of not more than three recent testimonials, not later than Monday, July 26th, 1937.

Town Hall, T. PEIRSON,
Stonehouse, Medical Officer of Health.
Plymouth.
July, 1937.

CITY OF PORT-OF-SPAIN.

APPOINTMENT OF A MEDICAL OFFICER OF HEALTH.

The Port-of-Spain City Council invite applications for the post of Medical Officer of Health for the City of Port-of-Spain.

The duties of the office are as set forth in the bye-laws made by the Central Board of Health and published in the Trinidad Royal Gazette of October 25th, 1917, page 1975-77.

Every applicant must be, or entitled to be, a member of the Medical Board of Trinidad and shall be the possessor of a Diploma of Public Health, Sanitary Science or State Medicine, registered or entitled to be registered in Great Britain and Ireland.

The office is a whole time one and pensionable under the provisions of the Municipal Corporations (Pensions) Ordinance, No. 29 of 1936. The salary attached to the post is £500 per annum, rising by equal annual increments of £25 to £1,000, with a travelling allowance of £75 a year.

The person appointed will be required to furnish a bond in the sum of £100 for the due performance of his duties.

Applications, stating age, qualifications and experience, should reach the undersigned at the Town Hall, Port-of-Spain, Trinidad, B.W.I., not later than July 31st, 1937.

Port-of-Spain, Town Clerk.
April 29th, 1937.
Trinidad, B.W.I.

CITY OF PORTSMOUTH.

ASSISTANT MEDICAL OFFICER OF HEALTH (Male).

Applications are invited from unmarried Medical Practitioners possessing the Diploma in Public Health for the following appointment:—

Assistant Medical Officer of Health and Second Resident Medical Assistant. Salary £500-£700, rising by annual increments of £25.

The gentleman appointed will be required to devote his whole time to the office, which will comprise duties in connection with Infectious Diseases, Tuberculosis, Maternity and Child Welfare, and any other duties assigned to him by the Medical Officer of Health. He will be required to reside at the Infectious Diseases Hospital.

There will be a deduction of £125 per annum in respect of the usual residential emoluments.

The position is designated as an established post under the Local Government and Other Officers' Superannuation Act, 1922, and the total salary will be subject to the statutory deduction of 5 per cent. under that Act.

Forms of application, together with conditions of appointment, may be obtained from the Medical Officer of Health, The Guildhall, Portsmouth.

Applications on the prescribed form, endorsed "Assistant Medical Officer of Health," together with copies of not more than three recent testimonials, must be delivered to the undersigned on or before Thursday, July 29th, 1937.

Canvassing, either directly or indirectly, will be deemed a disqualification.

The Guildhall, Portsmouth. July 12th, 1937. F. J. SPARKS, Town Clerk.

HULL CORPORATION HEALTH DEPARTMENT.

BEVERLEY ROAD INSTITUTION (HOSPITAL).

ASSISTANT MEDICAL OFFICERS.

The Corporation of Hull invite applications from registered medical practitioners, of either sex, under the age of 40 years, for appointment as Assistant Medical Officers at the above-named hospital, for a period of one year.

Salary is at the rate of £350 per annum, together with board, residence and laundry.

The Hospital Section contains 400 beds, and is equipped with *X*-ray and Ultra-Violet Light Departments.

In the case of one appointment, preference will be given to candidates with experience in medicine and in the treatment of mental diseases; in another, experience in surgery will be considered an additional qualification.

A form of application, together with conditions of appointment and a list of duties, may be obtained from the undersigned, to whom completed applications should be returned not later than 10 a.m. on Monday, July 26th, 1937.

Health Department, Guildhall, Hull. July 9th, 1937. NICOLAS GEBBIE, M.D., Medical Officer of Health.

BIDDULPH GRANGE ORTHOPAEDIC HOSPITAL.

Applications are invited from duly qualified and registered medical practitioners (unmarried) for the post of SENIOR HOUSE SURGEON at the above Hospital, which contains 88 beds. Salary is at the rate of £250 per annum, together with board, residence and laundry.

Candidates must have had experience in a General Hospital, and preference will be given to candidates who have had orthopaedic experience.

The appointment will be for a period of six months in the first instance and for a further six months at the option of the Council, but will not be renewable after that time.

Applications, with copies of two recent testimonials, should be sent not later than August 2nd, 1937, to Dr. F. Hall, School Medical and Child Welfare Department, County Offices, Preston.

Duties to commence October 1st, 1937.

GEORGE ETHERTON, Clerk of the County Council.

GLAMORGAN COUNTY COUNCIL.

PUBLIC ASSISTANCE COMMITTEE.

LLWYNYPIA HOSPITAL (RHONDDA).

APPOINTMENT OF RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners (male), under 35 years of age, for the appointment of Resident Assistant Medical Officer at Llwynypia Hospital (182 beds).

The person appointed will be required to assist under the direction of the Medical Superintendent in the general work of the hospital, and should have sufficient post-graduate experience in Midwifery to conduct all except the most difficult labours. Post-graduate experience in surgery will be an additional qualification.

Salary £350 per annum, rising by £25 annually to £450 per annum, with residential emoluments valued for superannuation purposes at £75 per annum.

The appointment, which will be terminable by two months' notice on either side, is a designated post under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass an examination as to physical fitness.

Applications, stating age and qualifications, and accompanied by copies of not more than three recent testimonials, must be received by the County Medical Officer, Glamorgan County Hall, Cardiff, not later than the first post on Friday, July 30th, 1937.

D. J. PARRY, Deputy Clerk of the County Council. Glamorgan County Hall, Cardiff. July 10th, 1937.

SURREY COUNTY COUNCIL.

JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER.

JUNIOR ASSISTANT MEDICAL OFFICER (either sex) required at County Sanatorium (300 beds), Milford, near Godalming. Resident experience in general hospital essential. Appointment is for six months, renewable for further six months. Salary £350 per annum, less a deduction of £100 per annum in respect of board, lodging and laundry. Appointment subject to the Staffing Regulations of the County Council. Forms of application from County Medical Officer, County Hall, Kingston-upon-Thames, to whom forms should be returned, with copies of three recent testimonials, by Saturday, July 31st, 1937.

COUNTY BOROUGH OF EASTBOURNE.

ST. MARY'S MUNICIPAL HOSPITAL.

RESIDENT HOUSE SURGEON.

Applications are invited from unmarried registered Medical Practitioners for appointment as Resident House Surgeon at the above Hospital.

Salary £150 per annum, with board, residence, etc.

The appointment is for twelve months, determinable at any time by one month's notice.

Application forms, together with conditions of appointment and duties, can be obtained from the undersigned. The application form, when completed, should be returned to me.

Avenue House, The Avenue, Eastbourne. W. G. WILLOUGHBY, Medical Officer of Health.

KENT COUNTY COUNCIL.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Resident Assistant Medical Officer at the County Hospital, Pembury (620 beds).

The salary for the appointment is £250 a year, with residential emoluments which are valued at £120 a year.

The appointment is a whole-time one, and will be for a period of one year only and not renewable.

Forms of application can be obtained from the Public Assistance Officer, Tonbridge Road, Maidstone, to whom applications must be sent by 10 a.m. on Monday, July 26th, 1937.

Sessions House, Maidstone. July 8th, 1937. W. L. PLATTS, Clerk of the County Council.

KENT COUNTY COUNCIL.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Resident Assistant Medical Officer at the Dartford Public Assistance Hospital (660 beds).

The salary is £250 a year, with residential emoluments, which are valued at £120 a year.

The appointment is a whole-time one, and will be for a period of one year only and not renewable.

Forms of application can be obtained from the Public Assistance Officer, Tonbridge Road, Maidstone, to whom applications must be sent by 10 a.m. on Monday, July 26th, 1937.

Sessions House, Maidstone. July 8th, 1937. W. L. PLATTS, Clerk of the County Council.

BOROUGH OF LUTON.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOLS MEDICAL OFFICER.

Applications are invited from registered medical practitioners for the above-mentioned appointment, at a commencing salary of £500 per annum, rising by annual increments of £25 to £700 per annum, with a car allowance of £40 per annum.

Applicants must hold the diploma of Public Health and have had experience in infectious diseases work. Experience in school medical and child welfare work will be an advantage. The duties will be largely clinical, but the post will offer an opportunity for experience in all the usual public health duties.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful applicant will be required to pass satisfactorily a medical examination.

Forms of application and full particulars relating to the appointment may be obtained from the undersigned, to whom applications, together with copies of three recent testimonials, enclosed in an envelope endorsed "Assistant Medical Officer of Health," must be delivered not later than Tuesday, July 20th, 1937.

Canvassing, directly or indirectly, will disqualify.

Town Hall, Luton. July 7th, 1937. W. H. ROBINSON, Town Clerk.

COUNTY BOROUGH OF DERBY.

COUNTY BOROUGH OF SOUTH SHIELDS.

THE GENERAL HOSPITAL (400 Beds.)

Applications are invited for the appointment of HOUSE SURGEON (male). Salary at the rate of £150 per annum for the first six months, and at the rate of £200 per annum for the second six months, together with board, residence and laundry. The appointment is for one year.

Forms of application may be obtained from the undersigned, and should be returned completed to him, together with copies of three testimonials, in a sealed envelope marked "House Surgeon."

Town Hall, South Shields. W. CAMPBELL LYONS, Medical Officer of Health.

COUNTY BOROUGH OF PRESTON.

SHAROE GREEN HOSPITAL. (250 Beds.)

JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER (female). Applications are invited from fully qualified and registered practitioners for the above appointment. Salary at the rate of £150 per annum, with full board and residence. The appointment will be for a period of six months, and at the end of this period the successful applicant may, subject to satisfactory service, be promoted to the post of Assistant Resident Medical Officer for a further period of not more than six months.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should reach the Medical Superintendent not later than first post on Saturday, July 24th, 1937.

COUNTY OF LONDON.

APPOINTMENT OF CORONER.

The London County Council invites applications for the appointment of a CORONER FOR THE COUNTY OF LONDON. The salary attached to the office is £1,700 a year, inclusive, and it is probable that the selected candidate will be allocated to the Eastern District of the County. The Coroner will be required to provide at his own expense any necessary office accommodation and clerical assistance, and to defray all other expenses of the office (including the services of an approved deputy, and, if appointed, an assistant deputy), except actual disbursements under the approved schedule of fees, etc. Candidates, who must be not less than 35 or more than 50 years of age on August 31st, 1937, must be barristers or solicitors and possess one of the qualifications required by section 1 of the Coroners (Amendment) Act, 1926. Due weight will be given to experience as deputy coroner and to the possession of a knowledge of forensic medicine. A pension is payable on retirement under an approved scale. The candidate appointed must give an undertaking to give his whole time to the duties of his office.

Application must be made on the official form, a copy of which, containing full particulars, may be obtained by sending a stamped addressed foolscap envelope to the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. Applications must be received by the Council not later than Tuesday, August 31st, 1937.

Canvassing disqualifies.

LONDON COUNTY COUNCIL

Applications invited from registered Medical Practitioners for temporary positions in the Council's service. (A) MEDICAL OFFICER (for minor ailments in children) for three sessions (2 hours each) a fortnight during school terms: Salary £99. (B) DENTAL ANAESTHETIST for three sessions (2½ hours each) a month during school terms. Salary £56 5s. At the LISSONIA SCHOOL TREATMENT CENTRE, 27, Grove Road, St. John's Wood, N.W.8.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (S.D.5), County Hall, Westminster Bridge, S.E.1, returnable by July 28th.

Canvassing disqualifies.

COUNTY BOROUGH OF BOLTON.

PUBLIC ASSISTANCE AND PUBLIC HEALTH COMMITTEE. TOWNLEYS HOSPITAL.

Wanted for the Townleys Hospital, Farnworth, near Bolton, an ASSISTANT MEDICAL OFFICER (male) for a period of one year.

The salary will be at the rate of £250 per annum, with rations, furnished apartments, attendance, etc.

Application forms, with conditions of appointment, may be obtained from the Public Health Department, Howell Croft, North, Bolton, and must be returned to reach the undersigned not later than Saturday, August 10th, 1937.

R. M. GALLOWAY, M.D.,
Medical Officer of Health.

Public Health Department, Bolton.
July 16th, 1937.

ROYAL BOROUGH OF KINGSTON-UPON-THAMES.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified and registered medical practitioners who are also registered in the *Medical Register* as the holder of a Diploma in Sanitary Science, Public Health, or State Medicine, for the post of Medical Officer of Health and School Medical Officer for the Royal Borough of Kingston-upon-Thames. The appointment is subject to the provisions of the Local Government Act, 1933, the Sanitary Officers (Outside London) Regulations, 1935, and the Local Government and Other Officers' Superannuation Act, 1922.

Terms and conditions of the appointment and form of application will be supplied on application to the undersigned.

The salary scale is—minimum, £950 per annum; maximum, £1,100 per annum; commencing salary to be determined as indicated in the conditions of appointment.

Applications on the prescribed form, and endorsed "Appointment of Medical Officer of Health and School Medical Officer," must be delivered to the undersigned on or before September 4th, 1937.

Town Clerk's Office, Guildhall, Kingston-upon-Thames.
A. W. FORSDIKE, Town Clerk.

July 15th, 1937.

CLAYTON HOSPITAL, WAKEFIELD.

TWO HOUSE SURGEONS required (male, British). Salary at the rate of £200 per annum, with board, residence and laundry.

Applications, together with copies of three recent testimonials, to be sent to the Secretary, Mr. T. F. W. MacKeown, M.A.

ESSEX COUNTY COUNCIL.

JUNIOR ASSISTANT MEDICAL OFFICER.

The County Council of the Administrative County of Essex invite applications for the appointment of Junior Assistant Medical Officer at the Black Notley Sanatorium, at which patients suffering from pulmonery and non-pulmonery tuberculosis are treated. Preference will be given to a candidate who has had experience in the treatment of pulmonary tuberculosis. The appointment is for a period of one year, and the salary will be at the rate of £250 per annum, together with board, lodging and laundry. The successful applicant will be required to pass a medical examination, and will be subject to the Council's Sick Pay Rules and Regulations, a copy of which will be forwarded on application.

Applications, in candidate's own handwriting, stating age, qualifications and experience, accompanied by copies of not more than three recent testimonials, should be addressed to me and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Monday, July 26th, 1937.

E. S. HOLCROFT,
Clerk of the County Council.

County Hall, Chelmsford.
July 13th, 1937.

CITY AND COUNTY OF BRISTOL. HEALTH COMMITTEE. SOUTHMEAD MUNICIPAL GENERAL HOSPITAL.

The Health Committee invite applications for the post of DEPUTY MEDICAL SUPERINTENDENT at the above-mentioned Hospital.

The salary will be £500, rising by annual increments of £50 to a maximum of £700 per annum, which includes board-residence and laundry, valued at £125 per annum, and this will be deducted from the salary payable.

The successful candidate will be required to contribute 5 per cent. of his salary and emoluments under the Local Government and Other Officers' Superannuation Act, 1922, for which purpose he will be required to undergo a medical examination.

Applications on forms to be obtained from the Medical Officer of Health, together with copies of three recent testimonials, must be sent to the undersigned by July 24th, 1937.

R. H. PARRY, M.D., D.P.H.,
Medical Officer of Health.

Public Health Department,
40, Prince Street, Bristol, 1.

CITY OF LEICESTER.

ASSISTANT MEDICAL OFFICER OF HEALTH (Three appointments—two females, one male).

The Council invite applications for three whole-time Assistant Medical Officers. Age not exceeding 40 years. Salary £500 per annum, rising by annual increments of £50 to £700. The appointments will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. The Diploma of Public Health, or similar qualification, is essential.

The duties will be principally in connection with the Maternity and Child Welfare and School Medical Schemes of the City Council, but the officers appointed will be required to carry out any other duties properly assigned to them.

One of the three appointments will be in connection with the supervision of the Municipal Midwifery Scheme, and the officer appointed (lady) must have had the necessary experience laid down for this appointment by the Minister of Health.

Applications, on a form to be obtained from the undersigned, should be accompanied by not more than three recent testimonials, and must be received not later than Saturday, July 24th, 1937. Envelopes should be endorsed "Assistant Medical Officer."

Health Department, Grey Friars, Leicester.
E. K. MACDONALD, Medical Officer of Health

July 17th, 1937.

COUNTY OF KINCARDINE

The County Council invite applications for the post of DEPUTY MEDICAL OFFICER OF HEALTH from medical men of not less than five years' standing and not over 40 years of age, with experience of maternity and child welfare, school and tuberculosis services. Salary from £600 to a maximum of £750, with placing according to experience, and increments of £25 per annum. Conditions of appointment and forms of application may be obtained from the COUNTY CLERK, Stonehaven.

HORTON GENERAL HOSPITAL, BANBURY, OXON (60 Beds.)

RESIDENT MEDICAL OFFICER (female) wanted for six months from the middle of August. Salary at the rate of £150 per annum, with board, residence and laundry.

Applications, stating age, qualifications and experience in the administration of Anaesthetics, with copies of two recent testimonials, to be sent to the undersigned not later than Saturday, July 24th, 1937.

RICHARD H. PRESCOTT,
House Governor.

CITY OF CARLISLE.

Appointment of ASSISTANT MEDICAL OFFICER for MATERNITY and CHILD WELFARE.

Applications are invited from medical women to take charge of the Corporation Maternity Home (12 beds), Ante-natal and Post-natal Clinics. The duties will also include School Medical Inspection Supervision of Midwives, and such other Public Health duties as may from time to time be prescribed. The duties of the respective offices will be carried out under the direction of the Medical Officer of Health.

Applicants must have had at least two years' experience as Maternity and Child Welfare Medical Officer, and should be in possession of the Diploma in Public Health, and preference will be given to candidates who have a special qualification in Midwifery.

The commencing salary will be at the rate of £600 per annum, rising by annual increments of £25 to a maximum of £700 per annum, and the lady appointed will be expected to commence duty at about the beginning of November.

The appointment is subject to the Local Government and Other Officers' Superannuation Act, 1922. Applications, endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, should be submitted to the Medical Officer of Health, 22, Fisher Street, Carlisle, on or before August 18th, 1937.

By Order,
FREDK. G. WEBSTER,
Town Clerk.

Town Clerk's Office, Carlisle.
July 13th, 1937.

CITY OF LIVERPOOL. PORT SANITARY AND HOSPITALS COMMITTEE.

RESIDENT ASSISTANT MEDICAL OFFICERS—(one male, one female). ALDER HEY HOSPITAL FOR CHILDREN. (952 Beds.)

Applications are invited for the above appointments, which fall vacant on October 1st, 1937.

The male appointment is for the Orthopædic Wards, which compromise 180 beds and include open-air wards for surgical tuberculosis. There is also a large amount of fracture and other orthopoedic work of an acute nature. Previous experience in othopaedic work is desirable and the Hospital affords ample opportunity for gaining experience in this work.

The female appointment is for the general medical and surgical wards of the Hospital.

Both the appointments are for a period of one year at a salary of £200 per annum, together with usual residential allowances.

Canvassing will be deemed a disqualification.

Applications to be made on forms obtainable from the Medical Officer of Health, Municipal Annexe, Dale Street, Liverpool, 2, to be endorsed "Resident Assistant Medical Officer," and returned to the undersigned not later that July 31st, 1937.

W. H. BAINES,
Town Clerk.

Municipal Buildings, Dale Street, Liverpool, 2.
July, 1937.

CITY OF SALFORD.

ASSISTANT RESIDENT MEDICAL OFFICER HOPE HOSPITAL. (1,200 beds)

Applications are invited for the post of ASSISTANT RESIDENT MEDICAL OFFICER (male) at Hope Hospital, Salford. The appointment will be for a period of six months. Salary £200 per annum, plus board, residence, and laundry. Further particulars and form of application may be obtained from the Medical Officer of Health, 143, Regent Road, Salford, 5, Lancs, to whom it should be returned not later than July 24th, 1937.

H. H. TOMSON,
Town Clerk.

CITY OF BIRMINGHAM.

Public Health Department.

Little Bromwich Hospital for Infectious Diseases.

JUNIOR RESIDENT MEDICAL OFFICERS (male)

TWO JUNIOR RESIDENT MEDICAL OFFICERS (male) required. Candidates must be unmarried and must have held previous resident posts in General or Children's Hospitals.

Salary at the rate of £300 per annum, together with board, etc., valued at £150 per annum. These appointments are limited to twelve months.

The officers appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by them.

It is not feasible to attend classes for the D.P.H. in conjunction with these appointments.

Forms of application may be obtained from the Medical Superintendent, Dr. J. McGarrity, Little Bromwich Hospital, Birmingham, 9, and should be returned to him on or before July 31st.

The Council House, Birmingham.
E. H. C. WILTSHIRE, Town Clerk.

NUNEATON GENERAL HOSPITAL.
(100 Beds.)

HOUSE SURGEON required immediately. Salary at the rate of £150 per annum, with board, residence, laundry, and certain other emoluments. The appointment is for six months in the first instance, and is one specially suitable to a medical woman.

Applications should be sent to the Hon. Secretary of the Medical Board, Nuneaton General Hospital, and may be accompanied by copies of two testimonials.

A TEMPORARY HOUSE SURGEON until September 30th next is also required under similar conditions to the post advertised above.

RESIDENT SURGICAL OFFICER.

The Medical Board will shortly be considering the appointment of a RESIDENT SURGICAL OFFICER as from October 1st next. The appointment would be for twelve months, renewable for two further periods. Salary £275 per annum, with board, residence, laundry, etc. Candidates should have had two or three years' hospital experience and should be capable of performing the simpler major operations of surgery and gynaecology.

Applications, accompanied by three copies of recent testimonials, should be sent to the Secretary of the Medical Board at the Hospital before July 26th.

THE CHILDREN'S HOSPITAL,
King Edward VII Memorial, Birmingham, 16.

RESIDENT SURGICAL OFFICER.
HOUSE PHYSICIAN No. 2
HOUSE SURGEON No. 2

Applications are invited for the above posts. Candidates for the post of Resident Surgical Officer must be *qualified and registered* and have held a responsible Resident appointment at a teaching Hospital. The salary attaching to the post is at the rate of £175 per annum, with board, residence and laundry. The appointment is tenable for one year as from October 1st, 1937.

Candidates for the posts of House Physician and House Surgeon must be *qualified and registered*. The salary is at the rate of £75 per annum, with board, residence and laundry, but if candidates have held satisfactory appointments at approved Hospitals the salary will be at the rate of £100 per annum. The appointments are tenable for six months as from October 1st, 1937.

Candidates should forward their applications, with proof of registration, and any credentials which they may desire to offer, to the undersigned on or before July 24th, 1937.

HAROLD F. SHRIMPTON,
July, 1937. House Governor

AYRSHIRE SANATORIUM, GLENAFTON, NEW CUMNOCK.

Ayr County Council invite applications for appointment as MEDICAL SUPERINTENDENT at a salary of £600 rising by annual increments of £30 to £750 a year, with free house, coal and light. The emoluments are subject to deduction of superannuation contributions.

Applicants must be registered Medical Practitioners with special experience in the Sanatorium Treatment of Tuberculosis.

Applications should be made by letter, should contain particulars with regard to medical training and experience and in particular with regard to experience and treatment of Tuberculosis, and should be lodged not later than July 21st, with JAMES R. LOCKIE, County Clerk, County Buildings, Ayr.

July 5th, 1937.

WEST NORFOLK AND KING'S LYNN GENERAL HOSPITAL.

HOUSE PHYSICIAN.

Applications are invited for the above post which is now vacant. Salary £175 per annum.

To have charge of Medical and Ophthalmic beds, also to act as Casualty Officer and Resident Anæsthetist. The post which is for six months in the first instance offers valuable experience in both In-patient and Out-patient work.

Applications with copies of recent testimonials, should be sent to the undersigned as early as possible.

JOSEPH F. SEARBANT, F.C.C.S.,
House Governor and Secretary.

THE PRINCE OF WALES'S HOSPITAL,
Greenbank Road, Plymouth.
(Formerly South Devon and East Cornwall Hospital.)

Applications are invited for the post of HOUSE SURGEON. Salary £120 per annum, with board, residence and laundry.

Appointment is tenable for six months, and is subject to renewal. Duties to commence July 21st. The Hospital is one which is recognised for the surgical practice required before admission to the Final Fellowship Examinations of the Royal College of Surgeons of England.

Applicants must be registered under the Medical Acts. Applications, stating age and qualifications, with copies of three recent testimonials, to reach the undersigned forthwith.

ARTHUR R. CASH,
July 5th, 1937. Gen. Supt. and Secretary.

ROYAL SALOP INFIRMARY, SHREWSBURY.
(150 Beds.)

APPOINTMENT OF RESIDENT HOUSE PHYSICIAN.

Applications are invited from fully qualified unmarried gentlemen for the appointment of Resident House Physician, vacant immediately.

Salary £160 per annum, with board, residence, etc.

The appointment is for six months, subject to re-appointment.

Resident Staff comprises Resident Surgical Officer, Resident House Physician, and two Resident House Surgeons.

The Resident House Physician is Resident Officer to the Medical Wards of the Hospital under the direction of three Honorary Physicians.

Applications, stating age, qualifications, experience, nationality, and accompanied by copies of three recent testimonials, to be sent to the undersigned forthwith.

Board Room. J. W. NOBLE,
July 7th, 1937. Secretary-Superintendent.

DEVONSHIRE ROYAL HOSPITAL, BUXTON, DERBYSHIRE. (300 Beds.)

(A National Hospital for Rheumatism and Allied Diseases.)

HOUSE PHYSICIAN (male). Salary £150, rising to £175 after three months' service (and prospects of promotion to Resident Medical Officer), with board-residence and laundry.

Candidates must be fully qualified and registered. The appointment is for a minimum period of six months, and may be extended for a further period of six months.

Applications, endorsed "House Physician," stating age, experience and qualifications, together with copies of three recent testimonials, must be forwarded without delay to the undersigned, from whom any further particulars may be obtained.

Considerable orthopaedic experience is available, and the appointment offers special facilities for any gentleman preparing a thesis or wishing to undertake special work, as the hospital contains all the necessary laboratory and other facilities for research. Canvassing will disqualify.

By Order of the Committee of Management,
A. PRESTON TURNER,
General Superintendent and Secretary.

NOTTINGHAM CITY ISOLATION HOSPITAL.

A TEMPORARY RESIDENT MEDICAL OFFICER is urgently required for a period of several months to take charge of the Hospital of 200 beds under the supervision of the Medical Officer of Health. Fever experience is desirable.

Facilities will be provided for the officer to gain experience of other branches of Public Health work, if desired.

Salary at the rate of £350 per annum, with board and lodging. Subject to two weeks' notice on either side.

Apply forthwith to the undersigned.

Guildhall, Nottingham. J. E. RICHARDS, Town Clerk.

APPOINTMENTS.—Contd.

VICTORIAL HOSPITAL, LOVEDALE, Cape Province, South Africa.

Applications are invited for the following posts:
(*a*) MEDICAL SUPERINTENDENT AND CHIEF MEDICAL OFFICER.
(*b*) TWO ASSISTANT MEDICAL OFFICERS, one of whom may be a woman.

The Victoria Hospital is part of the Lovedale Mission of the Church of Scotland, and Medical Officers must be in full sympathy with the missionary aims of the Hospital.

The Hospital contains 175 beds and is for Natives only. There is a large department for surgical tuberculosis in children; also an out-patient department.

The Hospital trains Native Nurses for the examinations of the South African Medical Council. It also co-operates with the S.A. Native College, Fort Hare, in the training of Medical Aids for service under the Union Government.

Medical Officers will receive salary on the scale £350 by £20 to £650 (or for woman—£325 by £15 to £500), initial salary depending upon professional standing and experience.

Further information can be given on application to: The Principal, Lovedale Institution, Lovedale, Alice, C.P., South Africa, or to The Foreign Mission Secretary, 121, George Street, Edinburgh.

METROPOLITAN HOSPITAL, Kingsland Road, E.8. (150 Beds.)

Applications are invited for the post of CASUALTY OFFICER AND RESIDENT ANAESTHETIST (male). Salary at the rate of £100 per annum, with board, residence and laundry. Duties to commence August 1st next. Candidates must possess a registered medical and surgical qualification of the United Kingdom.

Form of application may be obtained from the undersigned.

FRANK JENNINGS,
House Governor and Secretary.

THE PRINCE OF WALES'S HOSPITAL, Devonport. Plymouth.
(Formerly Royal Albert Hospital, Devonport.)
(64 Beds.)

Applications are invited for the post of JUNIOR HOUSE SURGEON. Salary £120 per annum, with board, residence and laundry.

Duties to commence immediately. Appointment is tenable for six months, and is subject to renewal, or promotion to the Senior position when this post becomes vacant. Applicants must be registered under the Medical Acts.

Applications, stating age and qualifications, with copies of three recent testimonials, to reach the undersigned forthwith.

FRANK ROWE.
July 20th, 1937. Secretary.

THE PRINCE OF WALES'S HOSPITAL, Greenbank Road, Plymouth.
(Formerly South Devon and East Cornwall Hospital.) (264 Beds.)

Applications are invited for the posts of HOUSE PHYSICIAN AND HOUSE SURGEON. Salary £120 per annum, with board, residence and laundry.

Appointments are tenable for six months, and are subject to renewal. Duties to commence immediately.

The Hospital is officially recognised for the surgical practice required before admission to the Final Fellowship Examinations of the Royal Colleges of Physicians and Surgeons of England.

Applicants must be registered under the Medical Acts. Applications, stating age and qualifications, with copies of three recent testimonials, to reach the undersigned forthwith.

ARTHUR R. CASH.
July 20th, 1937. Gen. Supt. and Secretary.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, Haverstock Hill, N.W.3.

APPOINTMENT OF CASUALTY OFFICER.

Applications are invited from unmarried registered medical women for the position of Casualty Officer at the Out-Patient Department of the Hospital at Bayham Street, Camden Town. The salary will be at the rate of £100 per annum, together with board, residence, etc., and the term will be for six months.

Applications to be made on a form which will be supplied by the Secretary, together with copies of not more than three testimonials, should be sent to the Secretary.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, Haverstock Hill, London, N.W.3.

APPOINTMENT OF HOUSE PHYSICIAN.

Applications are invited from unmarried medical men for the appointment of House Physician on August 1st next. The salary will be at the rate of £100 per annum, together with board, residence, etc., and the term will be for six months.

Applications, to be made on a form which will be supplied by the Secretary, together with copies of not more than three testimonials, should reach the Secretary not later than noon on July 22nd next.

ROYAL BERKSHIRE HOSPITAL, READING. (338 Beds.)

Applications are invited for the following Resident appointment:

One CASUALTY OFFICER (male).

The appointment is for six months, and candidates must be fully qualified and registered.

Remuneration at the rate of £150 per annum, with board, residence and laundry.

Applications, stating age and experience, with copies of testimonials, to be sent to the undersigned as soon as possible.

H. E. RYAN,
Secretary and House Governor.

ROYAL BERKSHIRE HOSPITAL, READING. (338 Beds.)

Applications are invited for the post of RESIDENT ANAESTHETIST (male), which falls vacant on August 15th, 1937.

Candidates must be fully qualified and registered and have had considerable experience in the administration of Anaesthetics.

The appointment will be for a period of not less than six months.

The salary of £250 per annum, with board, residence and laundry, will be paid to the candidate possessing suitable qualifications for the post.

Applications, stating age and experience, with copies of not more than three recent testimonials, to be sent to the undersigned as soon as possible.

H. E. RYAN,
Secretary and House Governor.

ST. JOHN'S HOSPITAL, LEWISHAM, S.E.13.

There is an immediate vacancy for the Resident post of CASUALTY OFFICER (male), tenable for six months at a remuneration of £100 p.a. Applications, with copies of testimonials, should be sent to the undersigned.

J. C. GILBERT,
Secretary-Superintendent.

HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, W.9.

HOUSE PHYSICIAN required September 1st. Applications are invited for this post. The salary is at the rate of £100 per annum and the appointment is for two months, which may be extended to eight months. Applications, accompanied by copies of three recent testimonials, should reach me by July 31st.

The accommodation at the Hospital does not permit of women graduates holding this appointment.

H. W. BURLEIGH,
Secretary and General Superintendent.

MANSFIELD AND DISTRICT GENERAL HOSPITAL.
(140 Beds. To be increased to 203.)

The Board of Management of the above Hospital invite applications for the post of HOUSE SURGEON (male). Duties to commence July 24th. Salary at the rate of £150 per annum, with residence, board and laundry. The appointment is for six months, and is renewable. The staff consists of Resident Surgical Officer and two House Surgeons.

Applications, stating age, qualifications and nationality, accompanied by not more than three recent testimonials, to be sent to the undersigned.

C. J. ADAMS,
Secretary.

THE NATIONAL TEMPERANCE HOSPITAL, Hampstead Road, N.W.1.

Applications are invited for the following post:
CASUALTY OFFICER (male). Salary £120 per annum, board, residence and laundry allowance being provided.

The appointment is for a period of six months as from August 1st. Preference will be given to those who have held a resident post. Candidates must submit applications, stating qualifications, age, etc., with copies of not more than three testimonials, by Friday, July 22nd, addressed to the Secretary.

KING GEORGE HOSPITAL, ILFORD (Near London). (207 Beds.)

HOUSE SURGEON (male) required immediately for six months. Salary £100 p.a.

Forms of application may be obtained from the undersigned, to whom they should be returned, duly completed, as soon as possible.

(Signed) G. AUSTIN HEPWORTH.
Secretary and Superintendent.

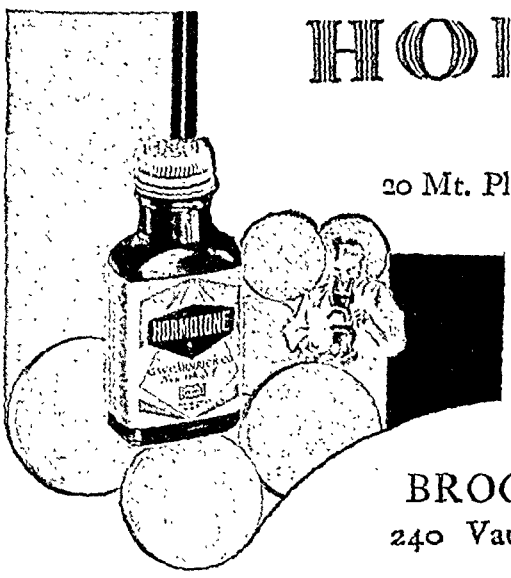
The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.
No charge is made to Principals for the introduction of Locum Tenens or Assistants.



1. DEVON COAST.—An 8/30ths share is offered to a THIRD PARTNER in an attractive Practice in a charming district. Receipts approximately £5,500 including Panel producing £850 and appointments £200. Good house with ample accommodation and nice garden available on rental £100 p.a. Premium 2 years' purchase. Applicant should be over 30, married, preferably with a degree and some surgical experience.
2. SHROPSHIRE COUNTRY.—Old-established PRACTICE producing about £2,300 p.a., for disposal. Panel of 1,300 patients. Minimum fee 3/6. Good house containing professional accommodation, 3 reception and 8 bedrooms. Small garden and garage for 3 cars. Freehold £1,350. Premium 2 years' purchase.
3. ESSEX COAST TOWN.—A ONE-THIRD SHARE is offered to a physician in an old-established Practice producing about £7,200 p.a. Panel produces about £900 p.a. Consultations 3/6 to 7/6. Visits 5/- to 21/-. There will probably be a choice of houses. Ingoing partner should be aged 35 or over and must have a good hospital experience. He should hold the M.D. or M.R.C.P.
4. BORDERS OF NORFOLK AND SUFFOLK.—A ONE-THIRD SHARE is offered in an old-established progressive Practice, the receipts of which for last year approximate £3,300. Panel of 1,400 patients. Expenses are low. There will probably be a choice of houses. Premium 2 years purchase.
5. ESSEX AND SUFFOLK BORDER.—Old-established PRACTICE available owing to ill-health. Receipts approximately £1,350 p.a., which includes about £140 per quarter from Panel and £100 p.a. from 2 appointments. Expenses are low. Good house in own grounds of one acre. Freehold for disposal £2,000. Accommodation consists of Professional rooms, with separate entrance, 2 reception and 5 bedrooms, lovely garden, garage for 2 cars. Premium 2 years' purchase. Nearest opposition 3 miles away.
6. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be 28-40, preferably hold a degree and must have their English Fellowship. Premium 2 years' purchase.
7. NORTH LONDON.—PRACTICE producing £758 p.a., including £322 from Panel and £135 from one appointment. Fees 2/6 to 3/6. Visits 3/6 to 5/-. Suitable accommodation available, 2 consulting rooms, waiting room and dispensary with separate entrance—2 reception rooms, 7 bedrooms.
8. [illegible] and appointments produce about £550 p.a. A share to give about £1,000 p.a. will be offered to a suitable applicant who should be capable of undertaking major surgery and be accustomed to good class work.
9. LONDON, S.W.—Old-established PRACTICE producing £1,500 p.a., with panel of 1,266 patients for disposal. Appointment and small club bring in about £85 p.a. House available contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. Premium £3,000.
10. KENT.—Country PRACTICE for sale owing to ill-health. Old established and producing for 12 months to 30/6/37, £1,477, of which about £460 comes [illegible] miles. Very good [illegible] disposal. Freehold
11. [illegible] required in an old-[illegible]eraging £7,000 p.a. Minimum fee 10/6. Ingoing partner should be about 30 to 33, married, hold a University degree and be used to high-class Practice.
12. NORTH-WEST COAST.—SEASIDE TOWN.—CONSULTING PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320. Minimum fee 2 gns. Suitable rooms available at inclusive rental of £64 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1½ years' purchase on actual receipts for first year.
13. HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc., Professional accommodation. Good garden and garage. Rent £55 p.a. Premium £1,250.
14. SUSSEX.—PARTNERSHIP.—A ONE-FIFTH SHARE (producing approximately £840 p.a.) is for disposal in a particularly sound good mixed class Practice situated in beautiful country and residential district within easy reach of sea. Fees from 3/6. Suitable house with 2 sitting, 6 bedrooms, separate professional rooms. Half an acre of garden, garage for two cars. Sport of all kinds and good schools within reach. Ingoing partner should be married, a graduate, and aged between 30 and 35.
15. NORTH-WEST COAST.—SUBURB OF FAVOURITE SEASIDE RESORT.—Well-established middle-class PRACTICE, steadily increasing, with good scope for further development. Gross cash receipts for immediate past 12 months £1,458, including Panel of about 400. Visits 5/- upwards, medicine extra. Very nice house with ample accommodation and garden can be rented at £104 p.a. Good sport and excellent educational facilities. Premium £2,004. Vendor retiring.
16. LONDON, SOUTH-EAST. [illegible] 30 years, averaging over £7[illegible] £25 p.a. Roomy house wi[illegible]
17. HERTS.—Old-established private PRACTICE for disposal owing to retirement of Vendor. Gross cash receipts approximately £1,400. Practice is a good mixed class one and the fees range from 3/6 to 15/-. Good house with ample accommodation, garden and garage on rental.
18. OUTLYING EASTERN SUBURB.—PRACTICE established over 40 years and averaging about £1,600 p.a., for disposal. Panel of about 2,000 patients. Suitable premises available at a rent of 20/- per week.
19. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¼ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house might be rented for a short period.
20. LONDON.—WESTERN SUBURB.—Old-established private PRACTICE [illegible]
21. [illegible] He has held it for the past 39 years. Income last year [illegible] of about 460 patients. Vendor previously [illegible] producing £450 p.a., which he relinquish [illegible]dered that anyone devoting whole time to the Practice would increase the receipts. Suitable accommodation available on rental.
22. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last 12 months over £1,300 p.a. Fees 3/6 to 21/-. Nice [illegible] 4 bedrooms, dressing room, etc. Modern conveniences. Garden, all kinds and schools within reach.
23. [illegible] F TWO GOOD TOWNS.—Old-[illegible]ICE averaging over £1,000 p.a., including Panel producing over £450 a year. Low expenses. Detached house in own grounds, containing 2 sitting rooms, 5 bedrooms, etc. Rent £70 a year. Premium £1,750.
24. LONDON.—NORTH-WEST.—Recently established and steadily developing PRACTICE producing for last 12 months approximately £1,000, and increasing at the rate of about £200 p.a. Suitable house can be rented or flat obtainable. Premium 2 years' purchase.
25. LONDON.—SOUTH-WEST (CROYDON AREA).—Old-established good middle-class PRACTICE producing for last 12 months £1,576 p.a., including Panel of about 1,300. Suitable house with 2 reception, 5 bedrooms, etc., can be rented at £80 p.a. Premium 1½ years' purchase. Illness reason for sale.
26. EASTERN COUNTIES.—Very sound unopposed middle and working-class PRACTICE in agricultural district averaging £1,150 p.a., including Panel worth about £460 p.a. Fees from 3/-. Nice house with 2 reception, 6 bedrooms, etc., electric light, garden, garage. Premium for Practice and house, £3,350.
27. NORTHERN SUBURB WITHIN 10 MILES OF HYDE PARK.—Recently established better-class PRACTICE, steadily increasing and producing for last 12 months £760. Panel of about 560 and appointments worth £40 p.a. Good freehold house with 4 bedrooms, etc., garden, garage. Price £1,450. Premium £1,450 or near offer. Vendor retiring.
28. EASTERN COUNTIES.—COUNTY TOWN.—Well-established PRACTICE averaging about £1,100 p.a., including Panel of 1,061 and clubs producing about £350 to £400 p.a. Vendor retiring through ill-health and age, and states there is excellent scope for increase.
29. NORTH-EAST COAST.—Old-established PRACTICE producing about £900 p.a., but stated to be capable of considerable increase. Choice of houses Partnership introduction given, as vendor retiring.
30. MIDLANDS.—FAVOURITE RESIDENTIAL TOWN.—Chiefly better class non-dispensing PRACTICE, producing for last 12 months over £1,600. Panel of 560 and one appointment worth £150 p.a. Fees 3/6 to 21/-. Very nice house with ample accommodation, garden and garage. Freehold for sale. Premium 2 years' purchase.
31. CENTRAL LONDON.—PRACTICE is worked as a "Lock-up" and averages about £1,000 p.a. Fees from 2/6. Suitable accommodation can be [illegible]rchase.
32. [illegible] established PRACTICE. Receipts for last [illegible] Panel of 350. House with 3 bedrooms, etc., garden and garage can be rented at £85 p.a. Premium £750.
33. SUSSEX.—ATTRACTIVE DISTRICT NEAR SEA.—PARTNERSHIP.—A ONE-FOURTH SHARE is offered (after preliminary assistantship of 6 to 12 months) in old-established Practice having good scope. Gross cash receipts for last 12 months approximately £3,275. Panel of about 1,300. Appointments worth over £300. Choice of houses on rental for ingoing partn[illegible]
34. NOR[illegible] p.a., [illegible] tion
35. SUS[illegible] owing to retirement of Vendor. Present receipts about £600. There is stated to be scope for increase as receipts have fallen owing to Vendor's illness. Panel about 650. Large house can be rented at £150, or purchaser could probably choose own residence.
36. LONDON.—SOUTH-EAST.—Old-established PRACTICE producing about £1,830 p.a., including select panel of 500. Fees from 3/6. Suitable house available with 2 reception, 5 bedrooms, etc. Freehold for sale. Premium 7 years' purchase.
37. [illegible] Garden. Garage. Price for freehold £2,000. Premium £1,250.
38. SOUTH CORNWALL.—FAVOURITE COAST TOWN.—Well-established PRACTICE averaging over £1,100 p.a., including selected panel of about 350. Fees from 5/-. Good freehold house for sale or smaller house available. Premium £2,000. Vendor retiring.

WANTED TO PURCHASE.—PRACTICE OR PARTNERSHIP producing £500 p.a. upwards, and situated within 2 miles of Highgate.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

An Endocrine Prescription *in* Dysmenorrhea *and* Amenorrhea

You can write an endocrine prescription in one word — a proper combination of the endocrine principles which are now known to initiate and control the menstrual process. Your prescription will have the advantage of being filled with fresh potent endocrine constituents. The formula is in accord with the most recent research on the endocrine glands concerned in regulating menstruation.

Valentine's Meat-Juice

In Typhoid Fever, Diarrhoea and Cholera Infantum, when it is Essential to Sustain the patient without irritating the Digestive Organs, the Ease of Assimilation and Power of Valentine's Meat-Juice to Restore and Strengthen has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

DIGEST OF TREATMENT

General Editor: GEORGE E. REHBERGER, M.D.

Volume I. August, 1937. No. 2.

Through *Digest of Treatment* the busiest physician can learn the latest developments in treatment by spending a few spare minutes. If he is interested in filing any one digest, he will find it simple to tear out, and a convenient size to fit into any notebook.
It is a monthly periodical designed to meet the needs of every practising physician or teacher of medicine.
Each month the Editorial Staff combs over 200 medical journals to get the newest and proven material to be digested and put into easily read form for the practitioner. Each issue contains forty to forty-five digests.
Unbiased selection of current opinions concerning the newer drugs are a feature.

Yearly Subscriptions Only. **12 Issues.** **25/- post free**

OPERATIVE SURGERY

The Ear, Air Passages and Neck (Vol. 3).

by DR. MARTIN KIRSCHNER,

with the collaboration of Dr. A. Lautenschlager and Dr. O. Kleinschmidt. Authorised translation by Dr. I. S. Ravdin and Dr. G. M. Coates.

460 Illustrations, mostly coloured. **Now Ready. 50/-**

There is at present no single work which covers the exact field covered by this one. It should be of help both to the general surgeon and the surgical specialist.

THE THYROID AND ITS DISEASES

by J. H. MEANS, M.D.

There is no comparable work on the medical treatment of the Thyroid and its diseases.

75 Illustrations. **25/-**

This book covers diagnosis and treatment. It is not only practical, but, we believe, the most informative book on the subject.

TUFT'S CLINICAL ALLERGY

JUST PUBLISHED!

This *entirely new* book by Dr. Louis Tuft is a systematic, splendidly organised presentation of *to-day's* knowledge of Allergy. But more than that, it is thoroughly *clinical*—decidedly practical—a book that will prove its worth again and again to both the General Practitioner and Specialist.

Dr. Tuft has clarified and simplified the subject of Allergy and its relation to the diagnosis and treatment of everyday diseases. He fully explains terminology, and gives a general description of the principles of the practice of allergy and the methods of diagnosis and treatment.

He gives extensive consideration to the Ætiologic Types, with full details of symptoms, diagnosis, and treatment. He places particular emphasis upon Clinical Manifestations, devoting *105 pages alone to Asthma*, full and detailed chapters on Hay Fever, Migraine, Allergic Rhinitis, and Gastro-Intestinal Allergy. There is an entire section in which Dr. Tuft discusses at length Allergic Dermatoses and Allergy in relation to the Specialties, including Allergy in Children.

Among the many features are dozens of prescriptions throughout the book, concise Summaries that conclude each chapter, numerous "Outlines" that give "thumb-nail" sketches of diagnostic procedures, treatments, etc. There are specific details on how to make tests and just what the findings mean. There is an especially practical Appendix that contains full descriptions of laboratory methods, directions for asthma and hay fever patients, etc.

This is a book designed to meet the requirements of *to-day's* medical practice.

CONTENTS of this NEW BOOK

Terminology and Anaphylaxis
Allergy in Man
Diagnosis, *including examination and tests*
Treatment, *including symptomatic treatment, drug therapy, prophylaxis*
Ætiologic Types, *including full chapters on serum, drug, food, pollen, bacterial and physical allergy*

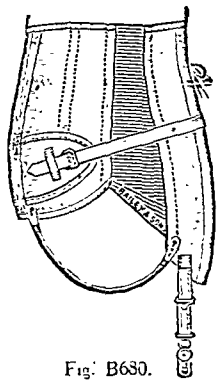
BAILEY'S BELGRAVE BELT.

Extra deep, dispensing with the use of corsets, giving both the abdominal and the waist support, lacing at the sides for regulation, with understraps or suspenders, as illustrated.

ELASTIC STOCKINGS FOR VARICOSE VEINS.

100 YEARS' REPUTATION FOR QUALITY AND COMFORT.

Uniform support maintained throughout.
Superior to any bandage; harm often being caused through unequal pressure in winding round the limb.
QUALITIES TO SUIT ALL PATIENTS.



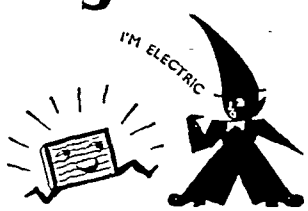


Fig. B680.

EXTRA DEEP BELT FOR ENTEROPTOSIS.

Dispensing with corsets. Supplied with understraps or suspenders, as illustrated. Made in Broche, pink or grey Coutille, elastic sides.

ELECTRIC FIRES
give better ventilation

While electric fires are recognised by many users as being the best and most hygienic heating medium, some medical men still think that the possible absence of chimney draught mitigates against good ventilation. But is this really so? In old-fashioned rooms an electric fire can stand in the grate, so that the chimney up draught remains. Some electric fires are specially made to fit into grates and provide for the regulation of this form of ventilation. An electric fire's convected heat is completely uncontaminated—it is pure, warm air, and as such can be used as a healthy and valuable warming medium in the room. Modern rooms constructed for electric heat have air bricks to give ready ventilation where it is needed—i.e., near the ceiling, which is better than near the floor where fireplaces stand. So surely, if properly instructed, the public gain nothing but good from the use of modern electric fires

Mr. THERM (of Harley St.) **says:**

'Gas fires keep you warm, but leave the air cool and fresh!'

The ideal fire would be one which had no effect on the air which surrounded you, but warmed your body through and through (in much the way that the sun does in winter in Switzerland). A modern gas fire comes near that ideal, because it warms very largely by radiation. It emits an unusually large proportion of the shorter infra-red rays — the rays that are so beneficial because they penetrate without scorching. A modern gas fire projects a comforting glow of warmth through the room, yet never overheats or dries the air. And, of course, it keeps the air always on the move — actually changing the air in a room three or four times every hour.

GAS for healthy heat

ISSUED BY THE BRITISH COMMERCIAL GAS ASSOCIATION

Whenever liver is indicated give

Hepferol

BRAND

Active Liver Principles with Iron in Palatable Granule form

4 & 8 oz. Boxes

In cases of pernicious anæmia and in all anæmic conditions which do not respond sufficiently to iron therapy alone HEPFEROL is especially indicated. Prepared from a standardised dry extract of liver with added iron. Readily assimilated by the organism. Constancy guaranteed.

When iron is indicated prescribe

IDOZAN

BRAND

5% of Fe Colloidal Iron Solution

8, 40 & 80 oz. Bottles

IDOZAN meets the fundamental requirements of an effective iron therapy. It establishes a strong positive iron balance, it is easily absorbed from the intestinal canal, providing a ready and abundant storing of surplus iron. IDOZAN is non-constipating, non-irritating and does not discolour the teeth.

SHOP WINDOWS

Who is not tempted to glance at the goods displayed in the shop windows which brighten the streets of every town? The subtle attraction of articles thus brought to notice cannot be explained by any immediate need to purchase. Indeed, the majority of the contents of shop windows have no immediate appeal. They are seen and a mental note is made which may well prove useful later on.

So it is with the advertisements in the *British Medical Journal*. Sometimes, it is true, the reader searches these pages to find a particular preparation or appliance for use in the treatment of a specific case. More often the advertised products are noticed and remembered pending their being required at some future time.

In this way an up-to-date knowledge of proprietary aids to medical practice can be maintained without expense and with very little expenditure of time.

Two helpful suggestions: Pages may be cut out and filed for future reference, and it is always worth while to mention the B.M.J. when writing to advertisers.

This pure, unsweetened Dole Pineapple Juice packed in vacuum-sealed tins is

HIGH IN NUTRITIONAL CONTENT

YOU can always count on unvarying quality and goodness in Dole Hawaiian Pineapple Juice. And the exclusive Dole Fast-Seal Vacuum-Packing Process preserves to a high degree the *desirable fresh-fruit constituents*. As a result, whenever your patients open a tin of Dole Hawaiian Pineapple Juice they are greeted by a tropical aroma, by a tangy flavour of juice that is unvaryingly delicious.

The original Hawaiian pineapple juice, Dole juice, has received the Seal of Acceptance of the American Medical Association's Committee on Foods. It not only contains important fresh-fruit elements, but is a natural source of vitamins A. B, and C.

J. K. Husband & Co., Ltd., 10 Eastcheap, London, E.C.3.

PREPARING FOR A LUAU... NATIVE FEAST—There are lots of preparations to be made before the luau is ready to be served. The poi must be pounded; the pig cooked in the imu—underground oven; pineapples, bananas, and other fruits are gathered; squid and fish must be caught on the reef; and the ti leaves gathered from the mountain side, in which to wrap the food and also to serve as covering for the table.

To the happy Hawaiian there is almost as much pleasure in all these preparations as in partaking of the delicious feast.

Here is a typical analysis of Dole Pineapple Juice:

Moisture	85.3%
Ash	0.4
Fat (ether extract)	0.3
Protein (N x 6.25)	0.3
Crude fibre	0.02
Titratable acidity as citric acid	0.9
Reducing sugars as invert sugar	12.4
Carbohydrates other than sugars (by difference)	0.38

P.S. If you will drop us a line on your letterhead, we will be glad to send you a free sample tin of Dole Hawaiian Pineapple Juice, the perfected pineapple juice.

for RELIABILITY

'CELLANBAND'

ANTISEPTIC PASTE-IMPREGNATED

BANDAGES

The CELLANBAND Dressing, when properly applied, furnishes a mechanical support vastly superior to crepe or rubber bandages, elastic hosiery, etc., and will usually be found sufficiently robust to enable the convalescent to resume reasonable light duties at an earlier period. CELLANBAND Dressings exercise a marked dehydrating and antiphlogistic effect, resulting in rapid reduction of oedema. Air-access to the tissues is not interfered with as in the case of gelatine dressings, so that evaporation of the skin secretions continues normally.

12/- PER DOZ. (7 yds. long, 4 in. wide)
SAMPLE BANDAGE **1/-** POST FREE

'SANOID'

STERILIZED LIGATURES

These ligatures are British both in production and materials. Their Tensile strength is well in excess of the recognised standards for particular sizes. A special process gives a surface-finish that ensures easy manipulation. SANOID Ligatures are exceedingly supple; the catgut straightens out and remains straight without "kinks" which are liable to cause breakage. Sterilization is carried out by the most up-to-date methods, and independent Bacteriological tests over several months in all cases gave negative results. Exceptional elasticity lessens the risk of necrosis.

The importance of The Qualitative Adequacy of the Diet

"... if the diet is unsuitable, the body cannot be properly constructed, neither can it function effectively."

(*Ministry of Health. First Report of Advisory Committee on Nutrition*, 1937, p. 6.)

The report quoted above stresses the need for ensuring that the whole community is provided with food which is qualitatively adequate. And it is acknowledged that foodstuffs containing vitamins play an important role in the economy of the body. Marmite is a yeast extract that is exceptionally rich in vitamin B_1 and the B_2 complex; it is prescribed extensively for its positive health-promoting properties. Marmite has many uses in preventive and curative medicine, and there is ample evidence of the benefit accruing from its regular inclusion in the diet.

ANAHÆMIN B.D.H.

The hæmatopoietic principle of liver

Whilst the introduction of liver (and, later, liver extract) as a therapeutic agent in pernicious anæmia marked a new era, the separation of the hæmatopoietic principle (anahæmin) from the reaction-producing protein substances wrought a revolution to such an extent that the injection of this highly-purified substance has now become a standard procedure for combating macrocytic anæmias.

The advantages of Anahæmin therapy are obvious; they are common to treatment in which a purified principle of constant clinical activity is administered in place of a crude extract which varies in action according to the amount of active principle present.

Indeed, the constancy of the activity of Anahæmin B.D.H. is so dependable that this product is employed for control purposes as an accepted standard for assessing the potency of liver extracts (*Brit. Med. Journ.*, April 3rd, 1937, page 730).

PITUITARY (POSTERIOR LOBE) EXTRACT B.D.H. (EXT. PITUIT. LIQ. B.P.)

PITUITARY (Posterior Lobe) EXTRACT B.D.H. is used as a matter of routine not only in obstetrics, but also for preventing surgical shock, for stimulating intestinal peristalsis, for relieving distension and gas pains following abdominal operations, and in intestinal toxæmias.

The administration of PITUITARY (Posterior Lobe) EXTRACT B.D.H. provides also a valuable safeguard against hæmorrhage following operations on the nose and throat. PITUITARY (Posterior Lobe) EXTRACT B.D.H. is prepared under strictly scientific control and is assayed biologically both for pressor effect and for oxytocic power; it is subsequently standardised to conform with all the requirements of the British Pharmacopœia. Its administration ensures, therefore, a uniform and dependable response.

FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research, acetyl-salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has, however, caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that "Alasil" definitely solves the problem of administering acetyl-salicylic acid in an effective form, being free from the risk of irritating the stomach or bowels or of causing general reactions.

A supply for clinical trial with full descriptive literature sent free on request.

In "Alasil" the desirable therapeutic effects of acetyl-salicylic acid are well exhibited by its calcium acetyl-salicylate moiety, while the presence of "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid, obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

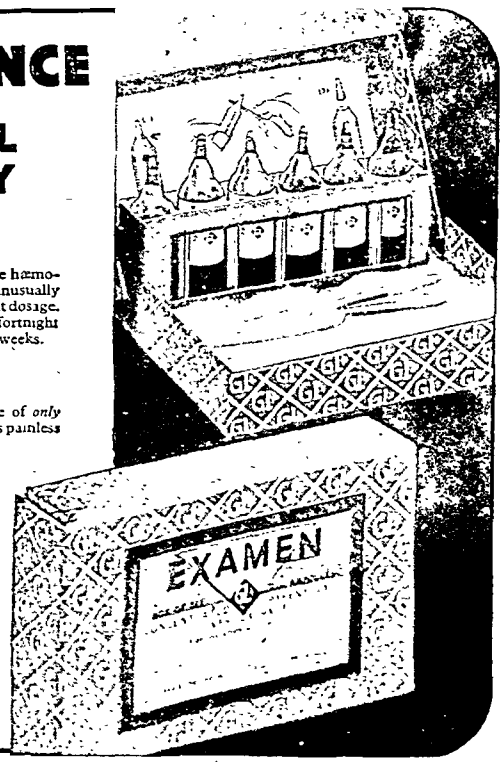
TRIPLE ADVANCE

IN PARENTERAL LIVER THERAPY

POTENCY

Each 2 cc. ampoule of Examen Liver Extract contains the hæmopoietic factor derived from 100 grams of fresh liver. This unusually high concentration permits of small and relatively infrequent dosage. *For treatment of pernicious anæmia:* 4 cc. and then 2 cc. each fortnight until blood count is normal. *For maintenance:* 2 cc. each 3-5 weeks.

PURITY



The high potency of Examen is contained in an average of *only* 10-15 mgms. of total solids in each 2 cc. ampoule, Examen is painless on injection and produces no allergic reactions.

UNIFORMITY

Extensive clinical trials preceded the introduction of Examen and established that its potency and purity are completely dependable. Furthermore, every batch of Examen is individually subjected to clinical test. Examen may thus be regarded with confidence as the most efficient liver extract available for the control of pernicious and other macrocytic anæmias.

GLAXO LABORATORIES LTD, GREENFORD, MIDDLESEX. BYRon 3434.

G.L.253

TAXOL

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

A major operation in progress in the operating theatre of a London Hospital.

ANTISEPTIC PROTECTION IN THE THEATRE

THE greatest danger in any operation is the risk of introducing bacterial micro-organisms into the system. Because of this, elaborate precautions are taken in the operating theatre to prevent infection. Modern antiseptic methods have succeeded in eliminating sepsis—once the surgeon's greatest fear and problem.

Risks of infection in everyday life, though less serious, are more numerous. In ordinary hygiene prophylactic measures cannot, of course, take the elaborate lines of the operating theatre, but fortunately the simple use of soap and water usually affords adequate protection against most forms of infection. But the degree of protection naturally depends on the antiseptic, antipruritic and germicidal qualities of the saponifying agent.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for purposes of general protection for over 70 years. It has substantial antiseptic and antipruritic qualities, and to-day, besides being specified by leading bacteriologists as the ideal everyday safeguard against infection, is used (according to the 1932 investigation of the Institute of Industrial Psychology) by doctors themselves more than any other brand of toilet soap. Wright's is the *only* soap to contain 'Liquor Carbonis Detergens' (Wright's), the valuable therapeutic used and recommended by eminent dermatologists. You can have every confidence in using Wright's in *your* practice and recommending it to *your* patients.

WRIGHT'S COAL TAR SOAP

The Safe Soap

AN ANNOUNCEMENT

THROMBIN — COAGULANT — MAW

If, in the course of treatment, it is necessary to supplement the natural processes of the body, there is general agreement that the use of the actual physiological principle is unrivalled, both for efficiency and for the absence of undesired reactions.

The control of haemorrhage is no exception, and in Thrombin-Coagulant-Maw we offer a preparation of the active principle—thrombin—which determines clotting. It is stable, extremely effective—we venture to think unusually so—and of course non-poisonous, and although only now available on a commercial scale, has had many years of successful trial.

It is obtainable in convenient units for immediate use, or where the requirements are more extensive can be supplied in suitable quantities for dispensing.

In boxes containing—

1 Tube THROMBIN

&

1 Tube Sterile SALINE

PER **1/9** BOX

Gastritis

Sanatogen is a *chemical combination* of ninety-five per cent. concentrated milk casein and five per cent. sodium glycerophosphate, which can be easily digested and absorbed even in cases of enteritis. Moreover, it stimulates a better utilisation of whatever ordinary food can be taken.

"*I had a female patient age 43 who was always rather below weight and nervy. She suffered severely from acute Gastritis following mild food poisoning and progressed slowly. She was put on carefully chosen soft foods, rest in bed, sedatives and Sanatogen, commencing with one teaspoonful three times daily. The last dose was taken half an hour before settling down for the night. She certainly improved. The stomach could receive and retain, with comfort, more food, and the nervous symptoms showed marked improvement, especially regarding sleep and general interest in life.*"—L.R.C.P. & S.

TWICE THE VITAMIN A POTENCY OF MILK

Why Cadburys Milk Chocolate is the ideal between-meal snack

IN THE LONG INTERVALS between the main conventional meals efficiency has been proved to flag and the nervous system to undergo strain. An 'extra meal'—a between-meal snack of real food value but preferably of slight bulk—averts this condition. To 'Eat More Often' without, however, increasing the total food-intake, is markedly beneficial in every normal case.

For this purpose the value of milk is well known, but especially in cases where the conditions of work render the consumption of milk difficult Cadburys Milk Chocolate will be found of even greater value. Handy and portable from the worker's point of view, it is highly nutritious and energising.

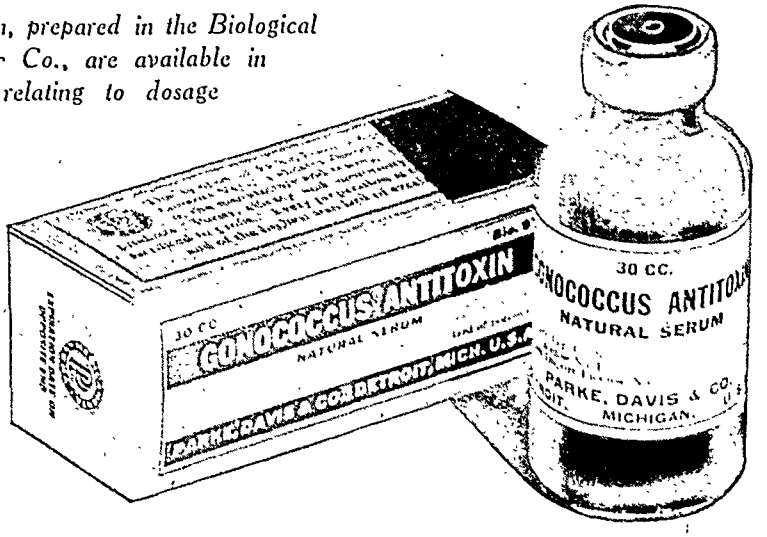
Recent tests made by the highest independent authority on samples of Cadburys Milk Chocolate taken from current production indicate that the chocolate contains 6 International Units of Vitamin A per gram as compared with a stated potency for milk of 3 International Units per gram.

It will thus be seen that the 'concentration' of the milk incidental to its conversion into Cadburys Milk Chocolate is far from affecting its original qualities.

1½ glasses of full cream milk contained in every ½ lb. block

Gonococcus Antitoxin

Parke, Davis & Co.



A Specific Antitoxin for the Treatment of Gonorrhœa

The treatment of gonorrhœa with a specific antitoxin was described in the *British Medical Journal*.* Although serum treatment in gonorrhœa is not new, previous work has been confined almost entirely to the use of antibacterial sera prepared by immunizing animals with cultures of the living organisms.

Gonococcus Antitoxin is prepared by immunizing horses with injections of a soluble toxin of the gonococcus, using a method similar to that used in the preparation of Meningococcus Antitoxin. Clinical trial of this Gonococcus Antitoxin has proved distinctly encouraging in acute and chronic cases—both complicated and uncomplicated—and has given results far superior to those obtained with other biological products hitherto available.

* "The Treatment of Gonorrhœa with a Specific Antitoxin." T. Anwyl-Davies, 1937. *Brit. Med. J.*, 1, 321.

Supplies of Gonococcus Antitoxin, prepared in the Biological Laboratories of Parke, Davis & Co., are available in vials of 30 c.c., and details relating to dosage accompany each package.

TRADE MARK 'TABLOID' BRAND

SULPHONAMIDE-P

0·5 gramme (*p*-aminobenzenesulphonamide or sulphanilamide)

Reduced facsimile

Administered by mouth, in hæmolytic streptococcal infections, such as:—

STREPTOCOCCAL SEPTICÆMIA, including PUERPERAL SEPTICÆMIA, SCARLET FEVER with COMPLICATIONS, ERYSIPELAS, TONSILLITIS, ETC.

Preliminary reports justify its trial also in Meningococcal Meningitis

Bottles of 25 products, 0·5 gm. at 2/- each
" " 100 " 0·5 gm. " 7/- "

London Prices to the Medical Profession

Literature to Medical Men, on request

O O O O O

SITE OF THE FIRST TEMPLE IN ROME TO ÆSCULAPIUS. BUILT ON THE ISLAND OF ST. BARTOLOMMEO, THE LOCALITY INDICATED BY THE GOD ON HIS ARRIVAL FROM GREECE, IT WAS RESORTED TO FOR RELIGIO-MEDICAL COMBINED WITH HYGIENIC TREATMENT.—Nothing in primitive Italic theurgic medicine appears to be analogous to the treatment practised in the Greek *Asklepieia*. It is possible that when Asklepios was brought to Rome, the first priest-physicians practising on the Tiber island were Greeks who had been invited to Rome. The cult of the Epidaurian god, whose name was latinised to Æsculapius, gradually became very popular, reaching its apogee in the second century A.D. Treatment consisted of incubation, ritual purification with fasting, prayer and sacrifice and magic incantations together with a general hygienic regimen. The view, reproduced from an 18th century engraving, shows the island at that time.

The Hearing Aid Par Excellence!

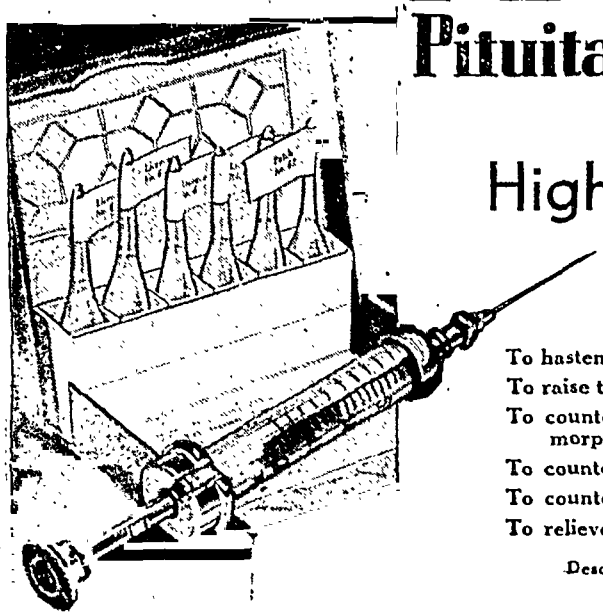
THE BŌNOCHORD *High Fidelity VALVE Amplifier*

For the patient in need of 100 per cent. efficient Hearing Aid, recommend a BŌNOCHORD High Fidelity Amplifier.

Convenient in size, they give distortionless reproduction over long distance, in general conversation, at meetings, etc.

A range of these new instruments is available for test by medical men and their patients, and will convince even the sceptical of their superiority over other types.

Let us send you further details of this new Allen & Hanburys' product, which is effective for 95 per cent. of deaf patients in need of artificial aid.



ALLEN & HANBURYS LTD.
ACOUSTIC DEPARTMENT,
48 WIGMORE STREET, W.1
Telephone: Welbeck 3903

PITIBULIN

Pituitary (Posterior Lobe) Extract

Trustworthy for

High Activity, Safety, and Stability

Some of its uses:

To hasten labour, usually in the second and third stages.
To raise the blood-pressure in collapse and shock.
To counteract intestinal paresis after operations, morphine poisoning, etc.
To counteract diabetes insipidus.
To counteract an overdose of insulin.
To relieve the pain of shingles.

Descriptive literature will be sent on request.

ALLEN & HANBURYS LTD. LONDON. E. 2.

ONE HUNDRED AND FIFTH ANNUAL MEETING, BELFAST, 1937

President's Address

SOME THOUGHTS ON MEDICAL EDUCATION

BY

R. J. JOHNSTONE, B.A., M.B., F.R.C.S., F.C.O.G.

Professor of Gynaecology, Queen's University, Belfast; Consulting Surgeon, Royal Maternity Hospital

Let me begin my address to you to-night by expressing again my thanks to the representatives of the British Medical Association for electing me to the Presidency—and you will permit me to add my appreciation of the warm and confident friendship of my colleagues in Northern Ireland who nominated me for this high office.

Our Association is not a mere trade union for collective bargaining. It is taking upon itself, it is having forced upon it, important public functions. It has advised on the formulation of policy and has assisted the plans of administrators. In this age of public health service it speaks with the authority of the medical profession behind it and is an important factor in affairs. While it has always maintained the honour and the interests of the medical profession, a review of its policy shows that it has never in that interest betrayed the community.

The Presidency of such an Association is no mean honour, and it is an honour enhanced by the distinction of those who have held the office before me. I have no intention of inflicting upon you a bead-roll of my predecessors, but it is my pious duty to commemorate the Presidents at your two previous meetings in Belfast. I do so with the more pleasure as both of them were my teachers, and of one I was for many years a colleague.

Presidents at Belfast in Earlier Days

When the Association first met here in 1884 Professor James Cuming was President. He was a physician of a type perhaps more common in those days than in these, a type which owed to the humanities and to medicine at least an equal allegiance. As an undergraduate one felt that a knowledge of Horace was possibly a better passport to his good graces than an acquaintance even with Fagge and Pye-Smith. His wide knowledge both of men and of medicine, his fundamental common sense, and not least his commanding presence made him a court of appeal as a consultant, and his judgements were delivered in measured phrase, in logical sequence, not seldom with ironic humour. In therapeutics he was not merely a sceptic—I speak now of his later years—he was an iconoclast. There is a story, probably apocryphal, that after a consultation he discussed at great length the diagnosis with the patient's doctor, who finally grew restive and said, "But what treatment am I to give him?" Cuming lifted a Burroughs Wellcome price list from his desk, handed it gravely to the inquirer, and said in his most impressive tones, "Begin at A and work through that."

In 1909 Sir William Whitla sat in the President's chair—also a physician, but with a difference. One evening he described to me at some length how he had almost persuaded the reader of his publishing firm that the split infinitive, as he used it, was an enhancement of English. In his own subject of materia medica and therapeutics he was a recognized authority. But his chief claim on the gratitude of his fellows was that he was a pioneer in a path of medical literature on which he has since had many followers. His *Dictionary of Treatment* came as a boon to many a harassed practitioner who had reached the end of his therapeutic resources. It was an immediate success, and retained its popularity through successive editions. It gained the distinction of translation into more than one foreign language, and one of Sir William's cherished possessions was a beautifully bound version in Chinese.

To his own profession Sir William was most generous. Besides his private kindnesses to his brethren in need he built and presented to the Ulster Medical Society as its permanent home the Medical, since his death the Whitla Medical, Institute. At its opening he told us that he had built it out of the profits on his *Dictionary of Treatment*.

His benefactions did not end with his life. He had been one of those who in the face of much opposition advocated the establishment of Queen's University. He had served it as Professor, as Senator, as Pro-Chancellor, and as member of the Imperial Parliament. When he died he left to the University his house and grounds as a residence for the Vice-Chancellor, together with a large share of his considerable fortune. The money has been earmarked for building, and when the Association next visits Belfast my successor will deliver his address in the Whitla Hall of the University.

Interest in Medical Education

The subject on which I have chosen to address you is that of medical education—partly because I am much interested in it myself as a teacher of graduate and undergraduate students of medicine ever since I got my qualification; partly because, if one may judge by the numerous criticisms of our present system of education I have read, my interest is shared by many others; and lastly, because medical education should be a matter of vital concern to

every practitioner and to every member of the B.M.A. Our profession cannot afford to recruit at a C3 standard. In this health-conscious age of ours public authorities are constantly launching one health scheme after another. As experts we ask for our collective advice to be taken and for our collective services to be employed. But the adminstrator has the last word, and while the specialist or the whole-time officer is practically immune from criticism, the incompetence or the carelessness of a few can be alleged as a reason for excluding the whole class of general practitioners from participation in a service. We are asking for our rights; but rights involve responsibilities, and if we are to enjoy the one we must be prepared to the last man to discharge the other.

I need not remind members of this Association of the many practical ways in which it shows its interest in medical education, "both postgraduate and undergraduate."

The critic of the medical curriculum assumes generally that we teachers at the end of five years should turn out a finished product, and goes on to blame us because we do not produce a finished general practitioner. No one expects us to turn out at the end of the five years a finished surgeon or anatomist or pathologist. Everyone recognizes that to form a specialist years of postgraduate study and experience are required. Are we to take it that the path which the general practitioner must follow to reach the mastery of his art is shorter and less steep than that trodden by the specialist? I should say "No." The specialist must know almost everything about his subject; the general practitioner must know something about almost every subject. He must learn to make his diagnoses without the skilled help which the specialist commands, and to carry out his treatment with makeshift appliances and with amateur nursing. He must acquire sufficient diplomacy to deal with unreasonable patients, with suspicious relatives, with inquisitive neighbours. He must keep in touch with the demands of public authorities and of public services. His responsibilities are if anything greater than those of the specialist, for he is the court of first instance, and on his decision the life of a patient may depend. His word may put a man in the dock or may even send him to the gallows.

Just as the finished surgeon must have had responsible experience of surgery, the finished general practitioner must have had responsible experience of general practice. The undergraduate's horizon is limited by the threatening figures of a court of examiners. Only when that grim spectre has faded is he free to take a view of the responsibilities which he must shoulder throughout the rest of his professional life—responsibility to his patients, to his own reputation, and, most important of all, to his own private conscience. The better trained the young graduate, the more quickly and the more competently does he take up the burden.

I may very pertinently be asked how, if practice is essential to form a good practitioner, can licensing bodies be justified in giving a licence to practise to those who have not had this experience. I can only reply that after many years as an examiner and as an inspector of final examinations I am satisfied that the dominant question in the mind of every examiner is "Is it safe to the public to allow this candidate to practise?" and that only when that question can be answered in the affirmative is he permitted to pass.

Clinical Study and the Undergraduate

As the practice of clinical medicine is the most important factor in forming the young practitioner and is to be his chief pursuit in after-life it is but natural that would-be reformers of the curriculum should demand that yet more clinical study should find a place in the education of the undergraduate. I should be the last to disagree, but do not let us be led into the fallacy of thinking that clinical training is the be-all and end-all of medical education.

A probationer nurse and a medical student have each approximately three years of clinical experience. The nurse's opportunities for clinical observation are infinitely better than those of the student. She probably sees at least as many patients, and she does not merely see them during a ward visit. She lives with them hour after hour and day after day, watches the course of their disease, notes its changing phases, and the effect of the methods of treatment that have been employed. She assists at consultations, and has the benefit of listening to clinical lectures. And she makes full use of her opportunities. Every one of us must acknowledge with gratitude the debt that we owe to the trained nurse for her help in diagnosis, in prognosis, and in treatment. But does her unrivalled clinical experience qualify her to take on the function of a medical practitioner? She would herself be the first to say "No." She lacks the background, the background of human anatomy and physiology and pathology, of knowledge of the human body in health and in disease, which the medical student has gained with much toil and sweat and against which his clinical observations are composed and the picture interpreted. It is the main business of a medical education to provide an adequate background and to teach how it should be used, and the more competently that work has been done the more valuable will his clinical experience be to the practitioner.

Importance of Practical Anatomy

I have put human anatomy in the first place as a necessary preliminary to clinical study. Teachers of anatomy are usually the most popular of professors among medical students, so it is only poetic justice that their teaching should be a favourite point for attack by the critics. And perhaps the commonest criticism is that such an unconscionable time is wasted by the student in the dissecting-room.

Is his time really wasted? The successful clinician takes little upon trust, and so far as is possible checks all his facts by his own personal observations. But in almost all the sciences which the medical student must study he is compelled to take most of his facts on trust. Practical classes permit him to verify a few of them, but he has neither the time nor the technical skill to go further. When he takes up practical anatomy he is not merely permitted and encouraged, he is required by his own personal observation to verify the statements of his teacher and of his textbook. This is an invaluable discipline, even if a knowledge of anatomy were of little use in practice. But anatomy is the large-scale map of the human body, and we have it on the authority of one who was both a scientist and a statesman that if we wish to get an understanding of peoples and of events it is essential to study large-scale maps.

Lectures and Lecturers

If the anatomist is Public Enemy Number One of the medical student, Number Two is undoubtedly in the eyes of the critics the lecturer. We who lecture might conjugate the verb something like this, "We are dull, you are falling asleep, they think we should be painlessly exterminated." The pity of it is that the critics are to some extent in the right. There are dreary lectures and dull lecturers, and that is a pity; for after one has

listened to a master of the art one is left in no doubt as to the superiority of the spoken word above the printed page in rousing interest in a subject and in presenting it in the round.

Teaching and lecturing are arts that can be learned, and nowadays a training in them forms part of the preparation of all primary and of many secondary school teachers. Would it not be possible that an institution such as the Postgraduate Medical School should give a course in lecturing, and that those who have designs on the teaching posts in our medical schools should be encouraged to take it out?

I do not propose to take up your time with further discussion in detail of the medical curriculum and of its critics. Doubtless it could be improved, but, so far as I have been able to find out, our medical students get a training certainly not inferior to that given in any other civilized country. Of course the curriculum is overcrowded, but fortunately the brain of the undergraduate is elastic and has a well-developed protective mechanism of forgetfulness, not likely to atrophy through disuse.

The Young Physician

However much or little the young graduate has retained of the many sciences he has become acquainted with, he has had a training in observation, in the use of his critical and his reasoning faculties, and in dealing with men, women, and examiners. He has the key to the vast storehouse of knowledge contained in medical literature, for he is familiar with its idiom. He now enters on the most important stage of his lifelong medical education. He now becomes his own teacher and taskmaster. He has had to learn to think like other people, he must now think for himself. Only thus can he transmute the ore of scientific knowledge into the gold of clinical wisdom.

In all but a few instances the neophyte begins his career under the tutelage of one of his seniors, either a member of a hospital staff or a general practitioner, and that senior has a great responsibility, for by precept and still more by example he may make or mar a promising practitioner. Both in this stage and later, when he has at last hoisted his own flag, the young physician need not want for aids in self-education. Nothing is more helpful than a circle of medical friends who are not ashamed to talk shop. Of much the same kind of value is the consultant who is willing to discuss cases at length. Lectures in a class-room may be indigestible fare for the undergraduate; delivered in a medical society they seldom fail to provide food for thought for the graduate student. His journals may be relied on to add to and to correct his store of knowledge.

Postgraduate Training

We have long had the postgraduate course for the few, but the National Health Insurance Act has now made it available for the many. If I might be permitted to criticize I think that most postgraduate courses try to administer to their medical patients what used to be called a "blunderbuss prescription," and that too much is attempted in too short a time. But these courses are still in their infancy. Some day we may see the general practitioner going back to his old school or to another school for a month, for three months, even for a sabbatical year, both to learn and to teach. And he will come back to his patients as he does from our present courses, not merely with his skill enhanced, but, what is perhaps more important, with his interests freshened and his enthusiasm rekindled.

There are possibilities of postgraduate training in the linking up of practitioners with hospitals, as Sir Farquhar Buzzard suggested last year. Leaving aside the difficult question of interference by one practitioner with the patients of another, there are many adminstrative problems to be overcome. With good will on both sides these should not be insoluble; but it will, I am afraid, be a long time before administrators can be brought to believe that a panel of doctors is just as efficient and reliable as, and gives no more trouble than, a whole-time officer.

Perhaps in the future all difficulties will be solved by the establishment of a State medical service. Like good democrats we shall always oppose it. But every fresh instalment of social and of public health legislation, every new chapter opened in the volume of State control, brings us steadily nearer to the totalitarian ideal, and when that has finally arrived I suppose we may say good-bye to the general practitioner as we know him.

The G.P. Past and Present

But he is still with us, and I ask myself, How does he compare with his predecessor of a generation back? His equipment is undoubtedly better, he has for the service of his patients a store of knowledge and an acquaintance with technical resources not even dreamt of when I was a medical student. But I take down a volume written more than forty years ago by one who had been a patient of many doctors, and when I read his judgement on our profession I realize that in the eyes of the patient—a critic who must not be lost sight of—qualities are at least as important as technical accomplishments. Let me quote a part of that judgement to you:

> "There are men and classes of men that stand above the common herd; the physician almost as a rule. Generosity he has such as is possible to those who practise an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in a thousand embarrassments; and what are more important, Heraclean cheerfulness and courage. So it is that he brings air and cheer into the sick-room, and often enough, though not as often as he wishes, brings healing."

One is proud to belong to the profession which merited such a tribute from Stevenson, for he was anything but a fool; but how little he says of the skill and of the training on which we set such store, and how much of virtues and of qualities unmentioned in any curriculum, and which no teacher whom I have ever met would undertake to impart. Does our scheme of education do nothing to foster them?

Medical practice and medical education has its repellent side, often sordid and sometimes disgusting. I do not think that many youngsters take up the drudgery of medicine unless they have as part at least of their motive a lively interest in humanity and some sympathy with human suffering. A hospital is the best of soils to foster such good qualities and to encourage them to develop into the most admirable of medical virtues. Close contact with men and women, the constant witness of their fortitude, their patience, their unselfishness in the face of pain, of disability, of death itself, is a more impressive lesson than the skeleton at the Egyptian feast, and only the most careless or the most callous can fail to benefit by it. Attendance in the wards and in the out-patient rooms, still more a residence in hospital, long a feature in Irish medical schools and soon to be introduced in the United Kingdom generally, is an education in behaviour no less than in clinical medicine. It is the better school for that,

as patients in British hospitals are treated as men and women with feelings which can be hurt and a personal dignity which can be outraged.

Conclusion

But I must bring to a close these disjointed remarks on medical education. I have no anxieties about our students. Their standard is as high as it ever was, and they are getting and taking an excellent training. To the seniors, of whom I am one, the two-edged compliment may be paid that it is impossible to improve us. But I do feel uneasy about the most important class in the profession, the young general practitioner in the twenties and the early thirties. Is panel practice giving him an assured income too soon? Is it taking away the incentive to study and to improve the standard of his practice? Is he sitting down at ease in Zion? I trust not, for it is upon him that we depend to maintain and to raise the prestige of our profession.

ELONGATION AND DILATATION OF THE COLON*

BY

J. R. LEARMONTH, Ch.M., F.R.C.S.Ed.

Surgeon to H.M. the King in Scotland; Regius Professor of Surgery in the University of Aberdeen

An approach to any problem of colonic disease must inevitably take into consideration the embryological origin of the large bowel, its adult anatomy, and its physiological duality.

Development

The colon is developed from two sources: (1) the midgut, supplied by the superior mesenteric artery; and (2) the hindgut, supplied by the inferior mesenteric artery, the juncture in the adult being about the middle of the transverse colon. Until the end of the first month the future small and large intestines are approximately of the same length, and the colonic rudiment is actually narrower than that of the small intestine. The second month sees the beginning of the rapid elongation of the primitive small bowel, but it is not until the fifth month that the calibre of the colonic rudiment begins to enlarge. The alimentary tube, originally straight, is rearranged after the second month by the rotation of the primitive bowel about the superior mesenteric artery; when this stage is completed the future caecum comes to lie anterior to the right kidney, the future splenic flexure has attained its adult position, and the future descending colon has been forced from its median position into the left flank by the rapid elongation of the small bowel. From this time until just after birth, when the adult anatomical arrangement is reached, there occur two processes which appear to be correlated with man's upright position: (1) descent of the caecum to the right iliac fossa as a result of elongation of the proximal part of the primitive colon, and (2) the disappearance of the dorsal mesentery from certain segments of the colon.

Normal Anatomy

To the complete peritoneal coat of the caecum may be added a short mesentery; the ascending colon is uncovered by peritoneum posteriorly. The transverse colon has a mesentery of varying length, which confers corresponding mobility on this segment. The descending colon lacks a mesentery, and the iliac colon up to the brim of the true pelvis is fixed to the parietes, whereas the pelvic colon forms a long free loop with a fan-shaped mesentery which allows a wide range of movement, the loop being four to ten times as long as the root of the mesentery.

Developmental Anomalies

It is not a surprising matter that a tube having such a complicated development should be a site of anatomical anomalies. Thus Treves found a mesentery to the descending colon in 36 per cent. of 100 cases, and to the ascending colon in 26 per cent. According to Dott's (1923) classification, anomalous development which might lead to elongation of the colon may be due to excessive growth in length of a segment, to deficient fixation of a segment to the abdominal wall, or to deficient fixation of the common mesentery of the terminal ileum and caecum, so that the caecum, or an ileo-colic segment, possesses a wide range of mobility. To this list may be added the plication of a segment of the tube which occurs when its mesentery is congenitally short, although the tube itself is of normal length or even elongated (Bernard and de Tayrac, 1935).

The Nerve Supply of the Colon

As a part of the alimentary canal the colon is innervated by both sympathetic and parasympathetic fibres. The "midgut" colon (caecum, ascending colon, and right half of transverse colon) derives its nerves from the plexus accompanying the colonic branches of the superior mesenteric artery; this is made up of contributions from the semilunar ganglia (sympathetic, from the thoracic splanchnic nerves) and from the right vagus nerve (parasympathetic). The "hindgut" colon (left half of transverse colon, descending and pelvic colon, and rectum) is innervated by nerves accompanying the inferior mesenteric artery, which are derived from the pelvic splanchnic nerves (sympathetic), and by branches arising from the hypogastric plexuses (parasympathetic, from the second, third, and fourth sacral nerves). The latter nerves pursue an independent course unrelated to the vessels, and have been traced (Mitchell, 1935) as far as the splenic flexure. Thus the proximal part of the colon is influenced by the cranial parasympathetic outflow (right vagus nerve), whereas the distal part is influenced by the sacral parasympathetic outflow. It has been shown (Learmonth and Markowitz, 1930) that stimulation of the sympathetic nerves is followed by inhibition of colonic activity. The parasympathetic nerves are motor to the distal colon.

The sphincter apparatus at the anus has two components: an internal sphincter, of unstriped muscle, which in man contracts on stimulation of the pelvic splanchnic (sympathetic) nerves (Rankin and Learmonth, 1930), and an external sphincter, of striped muscle, supplied by the (somatic) pudic nerves.

Physiology of Defaecation

Little need be added to the concise description of the mechanism of defaecation given in the admirable paper by Garry (1934), which I quote: "As in lower animals, eating food increases the activity of the human colon and frequently initiates a mass peristalic action leading to defaecation. This response was first noted by Macewen in patients with caecal fistulae. Subsequently the name gastro-colic reflex was applied by Hurst and by Hurst and Newton. . . . For our knowledge of the movements of the large bowel in *man* we are deeply indebted to Hurst. . . . Three or four times a day a massive peris-

* Read in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Belfast, 1937.

taltic wave drives the contents of the proximal colon bodily into the distal colon. Before and during the movement the haustral segmentation disappears. Holzknecht was the first to detect this mass movement in the human colon. In man the rectum is normally empty and faecal matter accumulates proximal to the pelvi-rectal flexure. As a result of one of the infrequent massive peristaltic waves faecal matter enters the rectum and the call to defaecation becomes clamant. In the act of defaecation itself strong peristaltic contractions occur throughout caecum and colon, the intra-abdominal pressure is raised by contraction of the diaphram and of the abdominal muscles, and the faeces are forced through the relaxed sphincters of the anal canal." The stimulus for the act of defaecation is distension of the rectum (Hurst, 1934; Denny-Brown and Robertson, 1935).

Possible Mechanical Results of Variations in Arrangement of the Colon

These may be considered under two headings:

1. *In the Caecum.*—It has been stated that when the caecum is unduly long and perhaps continued into an ascending colon possessing a mesentery, it lies constantly in the pelvis, and the absence of direct attachment to the abdominal wall deprives this part of the tube of a "hold," so that its contractions are less effective and its contents tend to stagnate. Formidable lists of symptoms have been attributed to caecal and colonic stasis produced in this way. At least in the adult, general and abdominal symptoms are not inevitably associated with mobility of the caecum; and attempts to provide an anchorage for it by operation have been almost entirely given up.

2. *In the Transverse and Sigmoid Colon.*—In these situations there are two theoretical possibilities: (*a*) that mobility conferred by an unusually long mesentery may lead to kinking of the gut or to volvulus; (*b*) that an elongated segment of colon possessing a mesentery of normal length would tend to be plicated and kinked (Bernard and de Tayrac, 1935).

Both these conditions are said to occur in the sigmoid of infants, which is stated by some observers to be relatively longer than in the adult. It is quite clear that, at least in later life, the colon may deviate widely from the normal arrangement (if there is such) without the appearance of abdominal symptons.

The rational view seems to me to be that the prolonged accumulation of gas and faeces in an elongated or mobile colon may lead to kinking, but that the cause of the accumulation is not the anatomical disposition of the colon itself.

Clinical Considerations

I am greatly indebted to Dr. William Brown, senior physician to the Royal Hospital for Sick Children, Aberdeen, for allowing me to utilize his clinical material. Members of the Section will be able to add their own experience; but I have found that the cases fall into certain groups:

1. Constipated children in whom the radiological examination discloses an anatomically and physiologically normal colon: the colon is normal in length and in mobility, and its contents are evacuated normally.

2. Constipated children in whom the radiological examination reveals an anatomical anomaly—for example, undescended caecum, mobile ileo-colic segment—and in whom satisfactory function can be produced and maintained by simple training and simple therapeutic measures.

3. Constipated children who suffer from periodic diarrhoea from the retention of faeces, and in whom the radiological examination after barium enema shows a distended colon, which the child can successfully evacuate after the bowel has been thoroughly emptied and trained.

4. Constipated children in whom the radiological examination after barium enema appears to show kinks either in the mobile parts of the colon or at a flexure, usually the splenic flexure. After simple treatment and training the constipation may be remedied, although the "kinked" appearance after a barium enema persists.

5. Constipated children in whom a barium enema outlines an elongated loop of colon, usually the pelvic colon, this appearance persisting after regular and satisfactory evacuations have been secured by appropriate treatment.

6. Constipated children in whom the barium enema discloses an elongated and distended colon; treatment may or may not result in satisfactory evacuation (megacolon). (Perhaps it is superfluous to remind members that the barium enema is a measure of the distensibility of the colon, and not necessarily of its tone. This important point has been emphasized by Hurst, who very rightly insists that the physiological efficiency of the large bowel can be assessed more accurately after a barium meal.)

From consideration of this clinical grouping it is quite clear that anatomical abnormalities of the colon do not inevitably cause constipation, and the success of a simple regime in cases showing elongation and/or dilatation seems to me to provide weighty evidence against the possibility of such anatomical conditions ever directly causing constipation. This view is supported by the observations of Khalik, Erfan, and Askar (1932), who found that anatomical variations in the length and calibre of the colon were common in infants who did not suffer from constipation. In the presence of faecal stasis it is conceivable that the possession of a long colon may increase and tend to perpetuate the condition by so altering the alignment of the large bowel that the *massive onward movement of its contents* preliminary to defaecation is impeded.

Treatment.—If I exclude cases of megacolon, which I shall deal with separately, it seems to me that certain general deductions can be made as to treatment. In the absence of evidence that anatomical peculiarity has any repercussion on colonic function, I would lay down the rule that surgical intervention in such cases is not indicated. It is true that successful cases of partial colectomy have been published, and that from time to time sympathetic neurectomy has been utilized in so-called intractable cases of constipation. I would like to make it clear that I do not now believe that neurological operations are ever indicated in constipation (apart from megacolon), whether the patient is a child or an adult. The severity of colectomy (even in young children) has been greatly reduced by the use of modern methods; but "successful" cases, to my mind, do not prove the efficacy of the treatment, but merely that a shortened colon can function adequately—which is a surgical commonplace.

Megacolon

"Megacolon can be defined as dilatation and hypertrophy of a part of the colon or of the whole colon, occurring in the absence of a gross obstructive lesion" (Adamson and Aird, 1932). It is a rare disease. [4 in 131,000 cases in a general hospital (Walton, 1930); 1 in 2,620 cases in a children's hospital (Hurst, 1934).]

The present view is that the enormous hypertrophy and dilatation so characteristic of the disease are the result of neuro-muscular dysfunction, and are congenital. The nature of this dysfunction is still problematical. The local changes in Auerbach's plexus described by Cameron may well, as Adamson and Aird (1932) point out, be secondary to other pathological changes in the wall of the bowel. The occasional association of dilatation of the bladder and/or ureters with megacolon focuses attention on their common nerve supply—pelvic splanchnic sympathetic

nerves and sacral parasympathetic nerves; it must be realized that over-activity of the one or under-activity of the other might produce the same result; and, indeed, Adamson and Aird have produced the condition in animals by dividing the parasympathetic nerves to the distal colon. Of neurogenic hypotheses mention may be made of spasm of the internal sphincter (Fenwick), achalasia of the sphincter ani (Hurst), and incoordination of the musculature of the colon, so that it does not relax before a peristaltic wave (Hawkins).

My own view is that the colon does not behave as if a terminal obstruction were present, for in such cases surgeons are accustomed to depend on early distension of the caecum as a constant diagnostic sign, and this is inconstant in megacolon. Adamson and Aird (1932) put the incidence of the disease as pelvic colon alone 37 per cent., with dilatation of the upper part or the whole of the rectum in 34 per cent. of cases. In only 25 per cent. does the dilatation extend to the ileo-colic valve, and in the remainder the descending, transverse, and ascending colon are involved with decreasing frequency. Radiological observations on the barium-filled colon show that it is active, although its activity is without result and may even give the impression of being purposeless.

My opinion at the moment is that the whole picture points to the presence of local segmental neuro-muscular incoordination when the disease does not involve the rectum, and that when the rectum is dilated there is added achalasia of the sphincter ani internus.

Treatment.—It has been shown by Morton and Scott (1930) that after spinal anaesthesia the colon may be able to evacuate its contents. As this procedure paralyses parasympathetic as well as sympathetic nerves one must conclude that the intrinsic neuro-muscular mechanism is adequate in such cases. In less severe types, preliminary enemata, training of the bowel, and the administration of liquid paraffin are usually adequate if the patient (and the parents) are intelligent and co-operative; when the rectum is involved, graduated dilatation of the internal sphincter, as suggested by Hurst, may also be usefully employed. When such simple measures are not effective the operation of sympathectomy may be considered, with the purpose of depriving the distal colon of its inhibitory nerves. Of the many technical procedures suggested, by far the most eclectic is that devised by Telford and Stopford (1934), and I consider that it should be employed exclusively. It consists in the resection of the mesially directed branches of the lumbar ganglia from the second to the fourth inclusive, and avoids the paralysis of the vasoconstrictor nerves to the legs which follows the (equally efficacious) emoval of the lumbar cords, and the sterility which follows esection of the presacral nerve in male patients.

The results of sympathectomy are distinctly good; in he series collected by Ross (1935), twenty-one out of wenty-nine patients were benefited, and many other surgeons have reported successes. My own experience is imilar. The mechanism of the improvement is obscure. Any explanation must take into account the often lramatic immediate improvement in function, which disposes of valves, kinks, or elongations as the essential ause of the failure of evacuation of the colon. Indeed (and this emphasizes the point made by Hurst), there is often little change in the appearance of the colon after a barium enema, though its function is satisfactory. I do not think one can go further than to say that the distal colon, under the unbalanced dominance of its extrinsic motor nerves, regains its physiological adequacy. It is interesting to note that when the urinary tract is dilated it shares in the improvement following sympathetic neurectomy (Adamson and Aird, personal experience).

Conclusion

In conclusion I advance as a basis for this discussion the view that elongation and dilatation of the colon are not primary causes of dysfunction of the colon, but incidental findings; and that their surgical correction should never be attempted. The condition of megacolon is an exception, in which the dilatation and elongation are part of the disease. It may be possible to persuade a megacolon to function adequately by medical treatment; if this fails, sympathetic neurectomy is likely to be successful.

PULP-SPACE INFECTION

BY

JAMES HARDMAN, F.R.C.S.

Late Surgical Registrar, Queen's Hospital, Birmingham; late Clinical Assistant in Surgery, Royal Infirmary, Sheffield

In the past attention has been drawn to the treatment of septic fingers and hands, notably by the works of Kanavel, Fifield, and Eckhoff. In attempting to follow their teaching I have collected the details of 183 cases of sepsis in the hand, among which were fifty-one of pulp-space infection. An account of my practice and treatment, with results and analysis of these cases, is here given.

Anatomy

In order to appreciate the difficulties met with in the treatment of pulp-space infection it is necessary to review certain fundamental anatomical points. The skin on the volar aspect of the finger is bound down to the periosteum on the front of the terminal phalanx by the dense fibrous tissue strands. The pulp is composed of fat, and is divided by the dense connective tissue framework into a series of loculi. Sweat and sebaceous glands lie in the fat, their ducts passing outwards to the epidermis.

Infection in many cases can be traced to a breach in the continuity of the skin, and is confined to one or a number of loculi in direct relation to the nidus of infection. An infection of these loculi tends to be directed backwards towards the periosteum of the terminal phalanx. Generalized involvement of the pulp is checked until the later stages by the fibrous walls. Inflammatory swelling, held within the limits of firm-walled loculi, is associated with greatly increased tension in the pulp, causing pressure, with diminished blood supply to the pulp and bone.

Classification

There are five main types of pulp-space infection, the classification depending on the time at which they are

seen and the site of infection. These cases may be grouped as terminal, lateral, and central infections. The central cases comprise those which are early and just

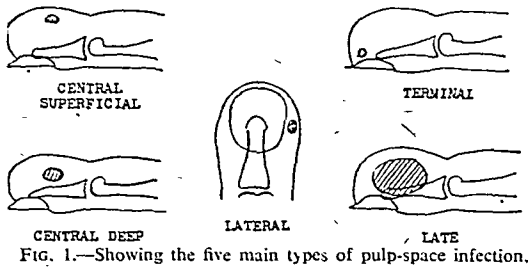

FIG. 1.—Showing the five main types of pulp-space infection.

beneath the skin and those which are late and the infection has passed deeply into the pulp. With neglect or inadequate treatment cases are seen in which the whole pulp has undergone disorganization; in many the terminal phalanx is dead, in part or the whole.

The series of fifty-one cases is grouped as follows: terminal, 4; lateral, 5; central—(*a*) superficial 5, (*b*) deep 27; late, 10 cases.

Aetiology

Of the fifty-one cases twenty-six knew of no cause, while of the remaining twenty-five, ten had sustained a small cut or roughening of the skin covering the pulp space. Ten knew definitely that they had had a piece of steel or a thorn in the finger, while four attributed the condition to receiving a blow on the finger; one case followed a burn.

Occupation.—Thirty-eight patients were working at a trade when they became infected. In this series four cases occurred in school children. The following table is compiled from the data available.

	Females	Males
Working in a trade	17	21
Not working, including housewives	12	1
	29	22

It is said that butchers, cooks, bakers, and fishmongers are prone to infection. In this series only five patients followed these occupations, whilst machine hands numbered twenty-two. Eleven others were of different trades, including carpenters, a glass polisher, a leather worker, and a typist. In a modern industrial town such workers constitute a majority.

The right hand was involved in twenty-six cases and the left in twenty-one. The thumb and index finger were most often affected. The digits involved were as follows: thumb, fifteen; index finger, fifteen; middle finger, six; ring finger, six; and little finger five times. There is no record in the remaining four cases.

Diagnosis

Early diagnosis of pulp-space infection must be established with certainty before making a radical incision necessary to obtain adequate drainage.

Symptoms.—Aching is the first indication to the patient that all is not well with his finger. He may realize that a trivial cut or one that has healed is about to give rise to further trouble. In twenty-five cases with a known cause the onset of symptoms followed the injury in the following times:

No. of Days	1	2	3	4	6	8-11
No. of Cases	9	2	4	3	2	5

Aching is first noticed when pressure is applied to the end of the finger; later it arises spontaneously and is present the whole time. Very quickly the pain becomes throbbing in character and the patient is incapable of sleep. In this series throbbing and inability to sleep have been taken as cardinal symptoms, and, with the presence of these, in only two cases was pus not found.

Physical Signs.—The pulp of the finger becomes swollen; swelling and induration are appreciable in comparison with the pulp of the corresponding finger of the other hand. In early cases a hyperaemic blush is found round the edge and base of the nail on the dorsum of the involved finger. Later the palmar aspect of the digit may become red and hot, but this is not an invariable finding. Tenderness is an indication of the part of the pulp space involved and the site of early pus formation. It is located by pressing on the pulp with a small probe. Induration is the cardinal sign of inflammation in the pulp, with the disappearance of normal fluctuation. Later with softening, and disorganization of the pulp architecture, fluctuation reappears. The case must be treated before the onset of fluctuation, for at this stage the phalanx is dead.

Treatment

Lancing.—The type of incision described as "lancing" is a vertical incision made in the length of the infected pulp space along its volar aspect. The length of the incision depends upon the courage of the patient and upon the determination of his doctor. Only those loculi in the line of the incision are opened, while those on either side remain inadequately drained. The patient feels some relief, but the finger continues to discharge. Early cases or those in which the infection lies just beneath the skin may be adequately treated by this incision. In hospital practice few cases of this type are seen, and it is therefore difficult to estimate the depth of the infection and to recognize the cases suitable for this treatment. When this incision is deemed to be the correct one it is urged that if resolution does not take place within twenty-four hours a further radical incision should be made. In twelve cases which were lanced a second operation was performed immediately it was realized that the treatment was inadequate. In five of these necrosis of the terminal phalanx did not occur; in five others a sequestrum was demonstrated on radiological examination and sequestrectomy performed; and in the remaining two a further operation for the removal of dead bone was carried out.

The U-shaped Incision (Fig. 2).—A curved incision is made round the end of the finger in front of the nail, cutting back into the pulp space, but never further than within half an inch of the distal skin crease, in order to avoid opening up the flexor sheath and so converting the infection into a tenosynovitis. By this method adequate drainage is obtained, and if performed early no complications arise.

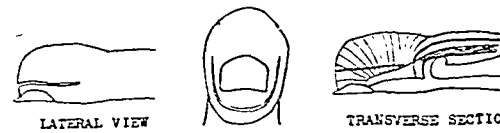

FIG. 2.—Showing the U-shaped incision for cases of terminal infection.

The incision is slow to heal, and does not leave an even scar. With experience of these disadvantages I ceased to employ this incision for the treatment of central infection. The U-shaped incision is the proper treatment for cases of terminal infection. The depth of the incision

is governed by the extent of the pathological changes found at operation.

Transfixion Operation (Fig. 3).—Two incisions are made, one on each side of the affected finger, 2 mm. in front of the edge of the nail, and the knife is passed across the pulp space just in front of the terminal phalanx. The incision extends to within a quarter of an inch of the end of the finger, and proximally to within half an inch of the distal volar crease. By this means all the fibrous tissue septa are divided posteriorly and all the loculi laid open. The palmar aspect is not turned back as a flap, and deformity and slow healing are avoided. There is no terminal scar over the sensitive pulp.

The full transfixion operation is recommended in early cases of central infection because it is impossible to assess the depth to which the pus has travelled backwards. If pus is not found, then with the knife in the transfixion incision cuts are made forwards into the pulp until pus is reached; care should be taken not to perforate the skin. In cases of lateral infection it is necessary to open only one side of the finger.

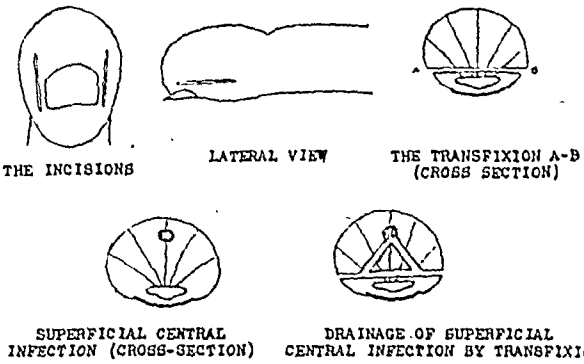

FIG. 3.—The transfixion operation.

Of the series of fifty-one cases this operation was carried out in thirty-three, and in only two did sequestrum formation occur.

Operative Technique

In hospital practice the infected finger is cleaned with spirit and a sterile towel is placed over the rest of the hand and forearm. Sterile gloves are worn and the patient anaesthetized with nitrous oxide. When a sufficient depth of anaesthesia is reached an assistant applies a tourniquet to the arm. The incisions recommended are then made; the knife is thrust through the pulp space from one lateral incision to the other, with the back of the knife facing proximally to avoid inadvertently opening the flexor sheath.

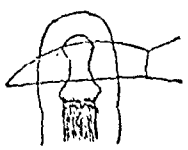

FIG. 4.

To transfix the pulp space in this way is not an easy matter owing to the toughness of the fibrous tissue. The tourniquet is essential to obtain a bloodless field. It is immediately realized when pus is reached, and if this is not seen the additional incisions described can be made. The pus is mopped away and sinus forceps are pushed into the incision so as to draw a piece of narrow glove-drain through. A magnesium sulphate dressing is applied with a covering of cotton-wool and a tight bandage is placed over all. The tourniquet is now released and the patient allowed to return to consciousness. After leaving the operating table he is rested for ten minutes, at the end of which time blood has soaked through the dressing, necessitating a further application of wool and bandage. The amount of haemorrhage from the incision into the vascular pulp is considerable, but by adopting this method the bleeding is controlled and the patient is able to return home.

Anaesthesia

It is important to use an anaesthetic which allows sufficient time to conduct the operation, without hurry, along the lines indicated; clear vision and a controlled patient are essential.

Gas-inhalation anaesthesia (nitrous oxide) was employed throughout this series: I believe that it gives full satisfaction. Ethyl chloride local anaesthesia was not used. The main objections to this are:

1. Frozen tissue is extremely hard, and it is impossible to make a satisfactory incision until the tissues commence to thaw.

2. Severe pain accompanies the great pressure necessary to cut through the hardened tissue and tends to check thorough treatment. When pus lies deeply it may not be reached.

3. It is impossible to carry out the transfixion operation with ethyl chloride local anaesthesia.

4. It is probable that the process may predispose to further tissue necrosis.

Adequate local anaesthesia can be obtained by digital nerve block at the base of the finger with 2 per cent. novocain infiltration. Local anaesthesia is contraindicated in cases in which the infection has spread beyond the pulp space.

After-treatment

The patient is seen next morning and the finger dressed. Care is taken to leave the rubber drain in position. A fresh magnesium sulphate paste dressing is applied and a short wooden finger-splint incorporated in the dressings. After forty-eight hours the rubber drain can be removed without discomfort and a further dressing given. In cases in which little pus was found the drain is left in for three days. In from four to six days elastoplast dressing is applied; this is kept on, according to the amount of discharge, until soiled. The patient attends at three-day intervals. When tissue destruction is marked separation of necrosed fibrous tissue may take at least three weeks. With elastoplast dressings the wound does not heal until separation is complete.

It is not my practice to use hot baths or fomentations. Hot fomentations had been given in many cases before the hospital treatment. Eckhoff condemns fomentations in the following terms: "The finger does not appear to be getting daily much worse, and the pain is disguised by counter-irritation in the form of hot bathing, hot fomentations, poultices, and other fatal local applications. These I would condemn at the outset. Bathing with or immersion in hot water only leads to generalized redness and tenderness of the finger, which makes diagnosis more difficult and is no lasting comfort to the patient. Fomentations and poultices tend to scald the part at first, and soon get cold and wet, and only serve to increase oedema when applied for more than twenty-four to forty-eight hours, and to spread infection, especially if there is already an open wound." It is my experience that in pre-operative treatment fomentations are of little value and lead to procrastination, and that infection subsides readily with adequate drainage.

The general toxaemia present cannot be ignored and must receive full treatment. The limb is splinted and carried in a sling, and in all cases the patient is advised to cease work and to rest in bed or in the garden. A large fluid intake, from ten to twelve pints daily, is of advantage until resolution is taking place.

Complications

Pulp-space infection must be treated seriously in the early stages before complications arise. Complications are difficult to treat and local deformity is unavoidable. When infection has spread beyond the pulp it may be impossible to check its course. The infection may pass to the tendon sheath, to the hand and palmar bursa, and in advanced cases to the space of Parona in the forearm. Many operations may be required to deal with these complications; amputations and contractures may cripple the patient or impair his working capacity. In unfavourable cases in the presence of virulent organisms, lowered resistance, or protracted course, life may be endangered by general toxaemia or systemic invasion by organisms. In this group of fifty-one cases complications remained local, and this paper is confined to the experience gleaned from these.

Sequestrum Formation

Sequestrum formation must be suspected in all cases in which the infection is of long standing or in which discharge persists. Ten cases of sequestrum formation were met with; of these seven had been lanced when seen, one came up with a sinus, one had discharged spontaneously, and one had been opened by a lateral incision. In the seven cases I believe that sequestrum formation resulted from inadequate drainage at the initial operation, further treatment having been postponed in spite of non-resolution of infection.

In hospital practice cases are referred in which the finger has failed to heal or discomfort and unfavourable progress continue after a preliminary operation. On examination a small wound may be found, and the finger is cyanosed, bulbous, and tender. In chronic cases the wound may be lined by granulation tissue and there is a constant discharge. In the chronic cases, or those in which satisfactory progress does not occur following the preliminary operation, it is essential to have the fullest possible understanding of the underlying pathological changes. A radiograph of the finger must be obtained, lateral and antero-posterior views. The findings must be interpreted with caution. The bone may be rarefied or absorbed in part, but such findings do not call for a surgical attack upon the phalanx, and at this stage adequate drainage may be provided and the bone left alone. Further radiographs must be taken from time to time and the bone watched. A fracture may occur across the base of the phalanx. In children the diaphysis may separate from the epiphysis. Bone erosion or sequestrum formation involves the shaft of the phalanx, and a small area of bone adjacent to the articular surface tends to survive. In this small fragment the flexor tendon is inserted. Sequestrum formation may take place in part or the whole of the phalanx. The dead bone retains its normal density and structure, and is sharply defined. These features form a striking contrast to the adjacent bones, which may have undergone absorption, causing changes in density and definition in the normal architecture. In later cases the terminal interphalangeal joint may be involved and diminution of the joint space or erosion of the adjacent bones may be seen.

Treatment.—The treatment of pulp-space infection complicated by sequestrum formation is governed by the degree of destruction of the involved phalanx. Bone destruction is revealed by the radiograph and by observations during the course of operation. When the radiograph shows a normal terminal phalanx except for a small sequestrum lying on the volar aspect, or the phalanx is eroded, the treatment consists in ensuring adequate drainage by the transfixion operation. The sequestrum is removed, or the phalanx scraped with a small spoon. Care must be taken to avoid the region of the base of the phalanx in which the flexor tendon is inserted. If the case is further advanced and the radiograph shows very extensive changes at the base of the diaphysis, with fracture, and the base of the phalanx is normal, treatment consists in adequate drainage by lateral transfixion; the whole of the terminal part of the phalanx is removed, the small proximal fragment, or in the child the epiphysis, is left to avoid infection of the interphalangeal joint and the flexor sheath. In very neglected cases in which there is involvement of the whole phalanx, including the terminal interphalangeal joint, the complete phalanx is removed through the transfixion incision. In cases in which the flexor sheath is not involved removal of the whole phalanx at this stage, carried out with care, does not add the risk of spread of the infection, because the flexor sheath may be shut off by adhesions.

Tenosynovitis

Tenosynovitis is a disaster of the first magnitude. It is bound to be followed by a prolonged convalescence, with a stiff and deformed finger, and in less favourable cases a crippled hand. The condition may arise from the natural spread of infection, but in practice this does not constitute the most important cause. In the majority of cases it follows in the wake of some surgical intervention. Spread of infection may be precipitated early in the case by extending an incision for drainage of the pulp too far proximally and opening the tendon sheath inadvertently. In later cases tenosynovitis is a complication arising from the treatment of sequestrum formation. It has been stressed in the treatment of cases associated with radiographic changes in the terminal phalanx that careful discrimination must be exercised before interfering with the bone at operation. In cases in which dead bone cannot be demonstrated it is better to provide adequate drainage and to review the case later. In the adult the base of the distal phalanx must be preserved in order to avoid opening the interphalangeal joint and flexor sheath. The base of the distal phalanx must only be removed in cases in which there is infection of the joint or tenosynovitis is present.

REMOVAL OF PHALANX, OPENING OF TENDON SHEATH
FIG. 5.

In cases seen following removal of the base of the phalanx a certain amount of drainage is provided through the tendon sheath being open at its extremity, and infection may remain localized to that part of the flexor sheath opposite the middle phalanx. When the flexor sheath is involved the patient is unwilling to move the affected finger, which becomes red, swollen, and slightly flexed. In two cases a small sinus discharging a thin serous fluid was seen at the distal skin crease. When the diagnosis of tenosynovitis is established lateral drainage must be provided immediately. A dead tendon must be excised

at a subsequent operation. In women and such men as desire it the finger may be conserved, but for the subject employed in manual labour better function may be obtained by amputation.

Summary

1. This paper is based on the experience gained in the study of 183 cases of infections of the hand, of which fifty-one cases were pulp-space infections.

2. Aching followed by throbbing and inability to sleep, associated with induration of the pulp, should be the established indications for immediate operation in pulp-space infection.

3. With adequate drainage inflammation in the pulp readily subsides. If resolution is delayed it is urged that the transfixion operation should be carried out.

4. Complications in pulp-space infection can be prevented by providing adequate drainage in the early stages.

5. In a chronic case it is essential to employ radiological examination before proceeding to treatment.

6. In the treatment of sequestrum formation and the prevention of tenosynovitis it is necessary to employ care in operation, and if possible to conserve the base of the distal phalanx.

ACKNOWLEDGEMENTS.—I wish to thank the honorary surgeons of the Queen's Hospital, Birmingham, for their courtesy in permitting me to carry out this work, and Mr. T. S. Donovan for his advice and criticism in the treatment of these cases. I am indebted to the honorary staff of the radiological department for help in the radiological work. In particular I wish to express my gratitude to Sister Arnold and the nursing staff for the kindness, care, and thought exercised in the treatment of these patients, without which it would have been impossible to conduct the post-operative care and follow-up. My thanks are also due to Mr. Coombs, radiographer to the Sheffield Royal Infirmary, for help with the radiographs. Finally, I wish to record my indebtedness to Dr. F. H. Kemp, clinical assistant in radiology at the Sheffield Royal Infirmary and Hospital, without whose help, criticism, and encouragement this paper would never have been published.

The annual meeting of the British Association will be held at Nottingham from September 1 to 8 inclusive, under the presidency of Sir Edward Poulton. Thirteen Sections have been arranged—namely, mathematics and physical sciences, hemistry, geology, zoology, geography, economics, engineering, anthropology, physiology, psychology, botany, ducational science, and agriculture. Presidential addresses f medical interest are as follows: Dr. G. W. C. Kaye, oise and the nation; Dr. F. L. Pyman, chemotherapeutic esearch; Professor F. A. E. Crew, the sex ratio; Dr. J. H. Hutton, Assam origins in relation to Oceania; Dr. E. P. oulton, new views on metabolism and nutrition, and growth n man; Dr. Mary Collins, tests in common use for the iagnosis of colour defect; and Mr. H. G. Wells, the nformative content of education. Other sectional discussions will relate to the contribution of physiology to he health of the individual and the community, protein hemistry, recent advances in genetics and cytology, motor ehicles and road safety, and the national food supply. Professor H. Hartridge will deliver a public lecture on illusions of colour. Further information about the programme of meetings, excursions, and accommodation in or near Nottingham may be obtained from the secretary, British Association, Burlington House, London, W.1.

ENTERIC FEVER*

BY

JOHN RITCHIE, M.B., Ch.B., M.R.C.P.Ed., D.P.H.

Medical Officer of Health, Dumfriesshire

I must begin by emphasizing that I speak only from the standpoint of a practising medical officer of health. In consequence most of what I have to say must appear somewhat elementary—a reiteration of what is already well known. But administration is mainly concerned with the application of established principles in changing circumstances, and the principles governing the prevention of enteric are no longer in doubt. Although many points of detail still await elucidation, our practical problem is the efficient utilization of the knowledge we already possess.

Reduction of Incidence and Mortality

It is not necessary to adduce statistical evidence as to the great diminution in the incidence of enterica in recent years. When a death rate drops, more or less steadily, from 388 per million in 1870 to 4 per million in 1935 there can be no serious doubt that the disease is becoming less common. Nor are statistics necessary to establish what is within the personal knowledge of senior members of the profession. A generation or two ago enteric was familiar to everyone in practice. To-day it is almost a clinical curiosity: there are many practitioners of standing and experience who have never had occasion to diagnose or treat a case.

But if enteric in its endemic form is no longer a constant menace, it is still capable of manifesting itself on occasion in formidable epidemics. The greatest water-borne outbreak on record—that which occurred at Barcelona and caused 1,847 deaths—was no further back than 1914. The outbreaks at Pforzheim in 1919, at Hanover and Rostoff-on-Don in 1926, and at Lyons in 1929 were all epidemics of the first magnitude, affecting thousands of people, while so recently as 1927 Montreal experienced a milk-borne epidemic, wherein 5,002 persons were infected and a tenth of them died. We have fortunately escaped tragedies of such dimensions, but sufficient outbreaks have occurred in recent years to remind us that enteric is still to be reckoned with as a serious problem in public health.

There is not much room for doubt as to the conditions which have determined the reduction of its incidence. Of no other infective disease can we say with the same confidence that sanitary activities have completely justified themselves. There is no reason to suppose that, in the absence of those activities, enteric would not be as prevalent to-day as it was in the middle of the last century. There is no evidence to suggest that it is less virulent or less capable of spread in a susceptible community, or that herd immunity to infection is greater than in former times. An almost savage scepticism is essential to the sanitarian, who is constantly tempted to believe that improvements in health are the result of his efforts to bring them about; but in this connexion scepticism appears misplaced.

The diminution of mortality, so far as Great Britain is concerned, came in three stages. From the early seventies it fell fairly steadily till 1885. From that date till about 1900 there was little improvement. At the

* Read in opening a discussion in the Section of Hygiene and Public Health at the Annual Meeting of the British Medical Association, Belfast, 1937.

beginning of the century the fall recommenced, and has continued till the present day.

One is aware of the temptation to over-simplification in discussing such phenomena, but there does appear to be justification for believing that the change in the incidence of the disease reflects the change in our views as to its aetiology. The hypothesis that insanitary conditions were the *cause* of infectious disease has been replaced by the belief that they are responsible for its spread, and the acceptance of the latter view has greatly influenced our attitude towards prevention. The first efforts of sanitary reformers were directed to environmental improvements—provision of better water supplies and substitution of sewers for privies. The success of those efforts was explained in terms of the pythogenic theory, Pettenkofer's ground-water theory, and the belief that enteric might be spread by sewer air—views that were held by observers whose opinions were entitled to all respect, but which, despite their value in promoting reform, are now regarded as ill founded.

Advances in Pathology

Further advance had to wait on the more accurate knowledge of pathology which accumulated during the last years of the century. The bacterial origin of the disease was recognized by the profession, the introduction of Widal's test put diagnosis on a sound basis, and the conviction that the enteric patient was the real source of enteric infection gained ground. Finally, the discovery of the potentialities of the carrier provided a credible explanation of the apparent *de novo* origin of epidemics.

Meantime, sanitary administrative machinery was being improved. More attention was given to the protection of food against gross contamination, and, in particular, the practice of removing enteric patients to hospital was increasing. This, I suggest, was one of the most important causes of the disappearance of endemic enteric, especially in rural areas, where "sanitary" improvement was often non-existent. I know many parishes where the disease, common during the 'nineties, has been practically unknown during the present century. There are still no sewers, the water supplies are still obviously open to pollution, flies still pass unchecked from privy to larder, but the enteric patient is no longer allowed to remain in a country cottage throughout the course of his illness, a constant danger to his immediate associates, a potential menace to the whole district.

Recently the carrier problem has been exhaustively studied, much information on preventive inoculation has been collected, and important advances in bacteriological technique have made it possible in many cases to obtain direct evidence on what in former days could only be inferred. But nothing has happened to modify the orthodox belief that the prevention of epidemic enteric is essentially a matter of protecting drinking-water and food, especially milk, from specific infection.

Now it is obvious that if the incidence of an infectious disease falls, not from natural causes but as a result of human effort, that effort must be maintained if recrudescence is to be avoided, and we must consider from time to time whether accumulation of knowledge justifies, or altered conditions demand, any change of our methods.

An indication that defensive arrangements are not yet perfect is the fact that water-borne and milk-borne epidemics still occur from time to time. These differ in their genesis. Recent investigations have shown that the life of *B. typhosus* in sewage may be considerably longer than was generally supposed, but the actual occurrence of water-borne epidemics seems to depend on recent and gross contamination, which disappears fairly rapidly—from an epidemiological if not from a bacteriological point of view—unless pollution be continuous. In any case, whether a sewage-polluted stream, a clean source accidentally fouled by excreta, or a well or leaking main contaminated by a faulty sewer be in question, infection is generally massive and comprises a vast bacterial flora in addition to *B. typhosus*. This appears to be the explanation of the occurrence of the widespread outbreaks of gastritis and enteritis which frequently precede water-borne epidemics. At Hanover about 30,000 and at Rostoff-on-Don about 40,000 cases of those conditions occurred just before the appearance of enteric, and the same thing has been observed on a smaller scale in many other places.

Another phenomenon, apparently due to the same cause, is the occurrence of a certain proportion of cases of paratyphoid fever along with the true Eberthian infection. In the two outbreaks I have mentioned about 6 per cent. and 16 per cent. respectively of the total cases were paratyphoid infections. There is not at present sufficient information on the point to speak with certainty, but it seems probable that this coexistence of typhoid and paratyphoid is specially characteristic of water-borne outbreaks, and indicates original massive contamination.

Infection by shellfish may perhaps be considered as a special form of water-borne disease resulting from gross and continuous pollution. It is interesting to note that in many instances shellfish infection has been associated with preliminary enteritis resembling that occurring before ordinary water-borne epidemics. The enteric-infected oyster still constitutes a serious problem in some places. That its importance for us has diminished is due in no small degree to research on the subject in Belfast.

Infection of milk is another affair. Though dairy hygiene still falls short of perfection, *gross* excremental pollution from human sources is unlikely. The amount of pathogenic material, whether derived from infected water or from a carrier's hands, is presumably small, but it is introduced into what may be an excellent medium for the growth of *B. typhosus*. It is this circumstance which makes prevention of milk-borne epidemics especially difficult. It is not possible to protect the milk supply against the risk of infection by a carrier or an unrecognized case of enteric. A dairyman, however conscientious, cannot be expected to recognize conditions which an experienced physician may have difficulty in diagnosing.

Protection of Water and Milk Supplies

As water and milk become infected in different ways they must be protected by different methods. Safeguarding of water is largely a question of finance, and there should be little need for discussion so far as large towns are concerned. Sources protected against pollution, adequate storage, efficient filtration, and, when necessary, chemical treatment constitute a succession of lines of defence sufficient to secure immunity. If one of those desiderata be lacking special emphasis must be laid on the others. Large communities, moreover, can provide expert supervision and sufficient staff to maintain efficiency. The experience of London in particular shows that by taking proper precautions the risk of water-borne infection may be reduced to negligible proportions.

The position of small towns, villages, and rural communities is different. Their water supplies are still frequently open to serious criticism, but the confidence re-

sulting from years of immunity and the relatively heavy financial burden entailed by improvements discourage sanitary reform. Such small supplies are often under the charge of an officer who has many other duties and who may have no real knowledge of water problems. Serious defects may exist unrecognized until they are discovered by accident or in the course of an epidemic. In a water-borne outbreak affecting sixty-five people, with which I had to deal some years ago, it was found that infection had occurred at leaking joints in the pipes conveying spring water to the collecting-tank. These might probably have been detected and remedied by a trained water engineer, but not unnaturally escaped the observation of the village factotum.

In such small communities, which may have provided sewers and gravitation water supplies many years ago but have neglected to maintain them in a proper state of efficiency, the risk of pollution increases steadily. Most medical officers of rural areas have probably seen contemporary examples of sanitary defects closely resembling those responsible for the classical water-borne epidemics of fifty years ago. It is totally erroneous to suppose that the improvement in water supply during the last quarter of the nineteenth century affected the whole country. There are still many places where the absence of water-borne disease depends on the lack of a source of infection rather than on safeguards against its spread. This is not likely to be remedied until water supply is recognized as a regional rather than a local problem and assistance given to those places whose own resources are inadequate to its solution.

A special danger in rural areas is the "auxiliary" supply, used to supplement an insufficient source of drinking-water. It is practically certain that it will be drunk occasionally. I have known one instance in which cases of enteric occurred at a farm which drew its drinking-water from a well but had an auxiliary supply from a stream near by. The patients were known to have drunk from the latter source despite warnings. About a mile upstream was a cottage provided with a water-closet draining to a cesspool which discharged into the stream. The tenant of this cottage proved to be a woman who had been shown several years previously to be a typhoid carrier, and we were successful in cultivating *B. typhosus* from the cesspool contents.

An adequately protected water supply is of importance in the prevention of milk-borne epidemics. It is of course possible that an outbreak originally due to polluted water may be continued by milk through someone connected with the dairy trade having been a victim of the water-borne infection. This was well exemplified at Santa Ana (Ca.) in 1924, when an epidemic due to sewage-polluted water and affecting some 370 persons was followed by a milk-borne outbreak of 200 cases in a neighbouring town, which had a separate water supply but derived much of its milk from a dairy at Santa Ana. The risk of such occurrences is very grave, and should enteric be prevalent in a dairying country it is essential that everyone connected with the milk business be kept under close supervision and all milk pasteurized till the danger of infection is past.

Again, milk may be infected through polluted water being used to wash utensils. Theoretically this should never happen, but until all dairies are fully equipped in accordance with modern ideas this risk cannot be ignored. There are cases in which milk has been infected during the cooling process, either by a leaking cooler allowing water to gain access to the milk, or, in the absence of a sufficient water supply, by the milk-cans having been set to cool in a stream which proved to be sewage-polluted. This appears to have caused the St. Catherine (Ontario) epidemic of paratyphoid fever in 1931. In this case 475 cases were traced to milk from two farms where milk-cans were cooled in a small creek that was contaminated by drainage from a district in which paratyphoid fever had been prevalent in the previous year. Such incidents show the need for securing that all water supplies, whether for drinking or for use in the production of milk or other foods, shall be protected against the risk of contamination. Neglect of this may have far-reaching consequences. A single case of enteric fever in a rural area may mean a big milk-borne epidemic in a distant city. Dr. Russell, then medical officer of health for Glasgow, said many years ago: "The status of enteric fever in Glasgow mainly depends upon rural sanitary administration." The experience of many large cities, both in Europe and in America, has proved that the truth of the observation is of general application.

The Carrier as a Cause of Infection

The main cause of milk-borne outbreaks is of course infection by a carrier, missed case, or contact who handles milk. Unfortunately his existence is generally unsuspected until the outbreak occurs, and even then it may be difficult to confirm. Proof of the carrier state entails detection of the causative bacillus in urine or faeces, and the intermittency of bacillary excretion by carriers may prevent this proof being obtained. Moreover, as I have learned by experience, samples submitted by a suspected carrier may have been borrowed for the occasion! Even after the carrier has been recognized the period during which he can be certified and put under restrictions is too short, and recertification may present difficulties. It should be recognized that after a year the carrier condition is permanent, and recertification should not be required.

Serological examination of suspects may help in detecting the carrier. The ordinary Widal test, however, does not give a sufficiently certain indication. I am not competent to discuss this point, but it seems possible that research on antigenic structure may eventually provide a reliable means of identification. Such a test would be of great value in practical administration.

It is a question whether anything short of universal pasteurization can protect against the risk of milk-borne enteric. The objection that this might lead to neglect of cleanliness in dairying could be met by fixing a sufficiently stringent prepasteurization standard, though the practical enforcement of such a standard would not be easy. Again, pasteurization is not an absolute safeguard, as the experience of Montreal and other places has shown. It would still be necessary to ensure that nobody capable of spreading infection was allowed to handle the pasteurized milk. A recognized carrier should of course be absolutely precluded from taking any part in the milk trade; indeed, in any business entailing handling food. But the control of carriers is so large a question, and raises so many issues, that I can only mention it here.

Conclusion

There are many other aspects of the subject which I should like to discuss did space permit, but there are two in particular which I emphasize in conclusion.

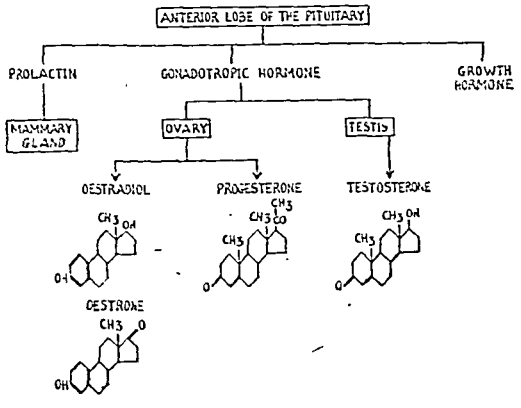
First, enteric fever should whenever possible be treated in hospital. The risk of infection is too great and too prolonged to justify home isolation, except in special cases, and it is in the patient's interest that he should receive

the expert nursing which is more important in this than in almost any other infectious disease.

Secondly, every outbreak should be fully studied by an expert bacteriologist. It seems that sometimes no more is done than the minimum necessary for diagnosis. This is not enough. The bacteriological history of each patient should be recorded as fully as the clinical. Investigation of the channels of spread should be checked by repeated examinations of sewage, water, milk, etc., and this may now be attempted with a reasonable hope of success. If it were done regularly our knowledge of and control over enteric fever would be materially increased.

THE SEX GLANDS

THEIR ANATOMY, PHYSIOLOGY, AND BIOCHEMISTRY *



BY

E. C. DODDS, M.V.O., D.Sc., Ph.D., M.D., F.R.C.P.

Courtauld Professor of Biochemistry in the University of London; Director of the Courtauld Institute, The Middlesex Hospital

Since subsequent speakers will discuss in detail the administration of various sex hormone products, I shall perhaps be able to fulfil my function as the opener by giving a brief summary of the present position with regard to therapeutic substances. The object of those who organize discussions such as this is to provide a practical survey of the subject, and I therefore propose to deal only with those substances which are of practical value and which can be obtained in an active stabilized form in the ordinary commercial market.

In the physiology of the sex glands it is necessary to consider two separate stages: first, the activation of the secondary sex glands by hormones of the anterior lobe of the pituitary; and, secondly, the hormones secreted by the sex glands after activation. The relation between the anterior lobe of the pituitary, the ovaries and testes, and the mammary glands can be seen in the following diagram, which is self-explanatory.

Hormones of the Anterior Lobe of the Pituitary

It is a well-known fact that the injection of extracts from the anterior lobe of the pituitary into immature animals will produce the precocious appearance of puberty associated with ovulation and the formation of corpora lutea in the case of the female; and in the case of the male descent of the testis and spermatogenesis will occur. Conversely, in the hypophysectomized adult animal all sexual activity ceases; and this again can be restored by the injection of a suitable extract. Up to the present, however, there is no such extract of the anterior lobe available for clinical trial.

It was discovered that in certain species the urine of pregnancy contains a substance capable of stimulating the ovaries of the immature animal. The test for the presence of this gonadotropic substance forms the basis for the well-known Aschheim-Zondek reaction; the substance was given the name of prolan by the original German investigators. The problem then arose as to whether this was a single substance or whether, according to the German view, it was composed of two parts—prolan A stimulating the ripening of the follicle, and prolan B being responsible for the luteinization of the follicle. The material which is at present on the market is agreed by nearly all workers to be almost entirely the luteinizing fraction. Therefore when we speak in subsequent discussions of the urinary gonadotropic hormone it must be borne in mind that we are dealing almost entirely with the luteinizing fraction.

It has recently been shown that the serum of the pregnant mare during certain stages of gestation contains a very active ovary-stimulating factor. This has been separated, and is available for clinical trial under the name of "antex." Most workers have agreed that antex is mainly follicle-stimulating, as opposed to the luteinizing fraction.

With these two substances—namely, urinary prolan and antex—it would appear that the clinician is provided with all the factors necessary for the control of ovarian secretion; but the clinical applications of these will be discussed by subsequent speakers. With regard to the chemical constitution of these substances little is known, but they are available in a stable and standardized form.

Hormones of the Ovary

Reference to the accompanying diagram will show that there are three substances—namely, oestrone, oestradiol, and progesterone. There are other oestrogenic compounds in addition to these, but since they are not available for clinical trial they will not be discussed here. Both oestrone and oestradiol, when injected into ovariectomized animals, will produce all the changes associated with the sexual cycle in the rodent. They will also cause the onset of premature puberty, and they only differ one from the other in their relative potency; oestradiol is by far the more potent of the two substances. Both oestrone and oestradiol are available clinically in the form of benzoates. These esters are used because their absorption is slower, and therefore with a single injection it is possible to get an effect very nearly approaching that of the normal function.

If either of these substances be administered to the monkey it is found that the menstrual cycle cannot be reproduced. Experiments on the ovariectomized rabbit have shown that a second factor is necessary for the complete reproduction of the cycle, and that this may be obtained from the corpus luteum. This material, called progesterone, has been isolated from alcoholic extracts of the corpus luteum, and has been characterized chemically. It is produced commercially in two ways—from the corpora lutea and also by the complex degradation of stigmasterol. If oestrone or oestradiol be in-

* Read in opening a discussion in the Section of Anatomy, Physiology, and Biochemistry at the Annual Meeting of the British Medical Association, Belfast, 1937.

jected into an ovariectomized woman for a certain length of time, and this be followed by injections of progesterone, a complete menstrual cycle can be instituted. It can thus be stated that the clinician is supplied with the necessary agents for the production of the menstrual cycle.

One of the great difficulties in the past has been the question of dosage. When these substances were first isolated their effects were studied exclusively on rats and mice and other small animals. This led workers to think and speak in terms of rat units and mouse units. Consequently when raw material first became available for clinical trial patients were injected with relatively small numbers of units. No progress at all was made until it was realized that sex hormones all follow the rules of body-weight ratio. It was thus shown that the use of the same material with identical methods of injection and smearing gave a rat unit which was roughly ten times the mouse unit—that is, in proportion to the body weight. It follows, therefore, that hundreds of thousands of mouse units will have to be given to the human subject to obtain similar results. This question of high dosage is apparent rather than real, and it is to be hoped that in the near future these substances will be prescribed like other therapeutic chemical agents, in terms of weight of the pure chemical substance.

Hormones of the Testis

The isolation of these substances has been the result of intensive studies of the effect of extracts of the testis on the comb growth in the capon. The fundamental observation was a demonstration that an alcoholic extract of bull's testis was capable of restoring the capon's comb to that of a normal cock. The most potent substance of known chemical constitution at the present time is called testosterone; the formula can be seen in the diagram. This hormone is produced by the complex method of sterol degradation, and it is standardized by its comb-growth-promoting properties.

Apart from promoting growth of the capon's comb, this hormone is able to restore the atrophied seminal vesicles of the castrated animal to their former size. The clinical applications of this substance have not yet been fully explored, since it is only comparatively recently that large amounts of material have been available for investigation. Its use has been suggested for the treatment of enlargement of the prostate and for replacement therapy in all conditions where the secondary male sexual characteristics have diminished. Its use in the treatment of enlarged prostate is based on the observation that prostatic enlargement caused by oestrone in animals may be successfully treated by the administration of testosterone.

Form of Administration

When the pure crystalline hormones were first isolated one of the difficulties at once appreciated was the question of absorption from subcutaneous injection. Earlier experiments had shown the fundamental difference of behaviour between the injection of hormones dissolved in oil and those administered in the form of an alcohol-aqueous solution. In general it may be stated that the ideal medium for injection is one which will allow a slow and steady absorption, thus imitating as nearly as possible the natural conditions. In the case of the sex hormones this is accomplished by their administration in the form of oily solutions. In order to slow up the absorption still more various esters have been prepared. Thus oestrone and oestradiol are available in the form of oily solutions of their benzoates. The benzoate is slowly hydrolysed in the body, thus giving a steady supply of the oestrogenic agent to the subject.

In the case of testosterone a very interesting observation was made when it was shown that the presence of certain fatty substances very much enhanced the activity. Out of this has developed the ester testosterone propionate, in which form the hormone is available to-day. This ester is many times more potent than the free testosterone, and the whole question of potency of this group of substances is very largely bound up with the type of ester which is administered.

Evaluation of Results of Therapy

This presents little difficulty in the treatment of amenorrhoea, since success or failure is apparent. On the other hand, in the treatment of menopausal disturbances it is difficult to exclude the psychological element. Recently, however, the introduction of the vaginal-smear method has provided us with an entirely new technique for the evaluation of therapeutic measures in the menopause. It has been shown that the vaginal smear of post-menopausal women presents an entirely different cell picture from that of pre-menopausal women, and that suitable therapy will transform the post-menopausal smear into the pre-menopausal one. Subsequent speakers will describe their experience with this new method.

Conclusion

In conclusion, it can now be stated with certainty that the labours of the biologist and the organic chemist have placed in the hands of the clinician a series of very powerful therapeutic substances. No longer is it possible for the practitioner to doubt the activity of endocrine products. If he will but take the trouble it is possible for him to obtain highly potent, stable, and standardized preparations of hormones; and let us hope that the discussion which is to follow will give him some indication of the possible uses to which he can put these substances.

H. G. Huber (*Kinderartzl. Prax.*, 8, 152) states that while encephalitis is not a rare event in certain infectious diseases, such as influenza, measles, whooping-cough, varicella, mumps, small-pox, scarlet fever, and vaccinia, only a few cases have been recorded of its occurrence in typhoid fever. In the cases described by Elias, Schächter, and Lemlakis typhoid encephalitis was manifested by bulbar, mesencephalic, spastic, cerebellar, or cortical symptoms. The bulbar type with tachycardia and polypnoea is usually fatal; paralysis of deglutition is rare. In the mesencephalic type the symptoms are hyperkinesia, pseudo-lethargy, oculomotor palsies, and in rare instances facial paralysis; while in the cortical type hemiplegia, epilepsy, and aphasia appear. Huber records the case of a girl, aged 11, who in the second week of typhoid fever developed stupor, facial paresis, spasms of the extremities, slight nuchal rigidity, Kernig's and Brudzinski's signs, and well-marked aphasia. The tuberculin reaction and *x*-ray examination of the chest were negative. Complete recovery took place after ten weeks' illness.

Clinical Memoranda

Undulant Fever: Death from Paralytic Ileus

A case of undulant fever which terminated fatally in a man aged 64 seemed interesting enough to warrant its being placed on record.

CASE REPORT

This patient's illness began on January 16, 1937, and he was first seen on account of an attack of faintness. He then had a blood pressure of 123/68 mm. Hg. and a pulse rate of 88, and he complained of abdominal colic and distension. A nervous breakdown in the previous year had made him very apprehensive about his health, and I (A. O.-E.) imagined that the irritable condition of heart and bowel was due to vagla activity. After a few days in bed his heart condition improved and his pulse rate was 72 and his blood pressure 136/76 mm. Hg. With one tablet of allonal (5 grains) at night he slept well, and the colic had abated, although the stools were unformed and frequent. His temperature had been normal throughout.

On January 25 he became decidedly worse, and a mixture of bismuth carb. 10 grains, salol 5 grains, and chlorodyne 10 minims seemed to have no effect. Dr. Parry saw him with me in consultation, and laudanum was substituted for chlorodyne, but the stools were still very frequent and were completely unformed. On February 3 Dr. Parry kindly took over the case as I had to go on sick leave. On the same day the patient was transferred to a nursing home in Hove. A blood test was taken, and the report of the pathologist was as follows:

Widal's reaction for typhoid (H and O), paratyphoid A (H), and paratyphoid B (H and O) is negative; no agglutination in any dilution. The reaction for *Br. abortus* is positive, showing complete agglutination up to a dilution of 1 in 320 and nearly complete agglutination in 1 in 640.

At the time of his removal he was at the end of a wave of fever, and for three days his temperature was practically normal; it then gradually rose to about 102° F., and this wave continued until his death four weeks later. The immediate cause was paralytic ileus. This began about two weeks before death with gradually increasing abdominal distension, which reached such a stage that large coils of distended intestine were visible. He still had infrequent liquid motions, and flatus passed freely when a rectal tube was inserted. For the condition of ileus the following remedies were tried: enemata of turpentine, enemata of asafoetida, turpentine stupes, hot fomentations, and an electric pad to the abdomen; injections of pituitrin and of acetylcholine, and doses by the mouth of oil of peppermint, oil of cloves, and oil of izal, all in keratin-coated capsules: but nothing had any appreciable effect, and he died of toxaemia about six weeks after the beginning of his illness. No trace of *Br. abortus* was found in any of the cows in the herd from which he obtained his milk supply.

I (L. A. P.) had the kind assistance of Dr. Donald Hall, who attended the case with me on several occasions. Lord Horder, who also saw the case, told us that paralytic ileus was at one time quite common in typhoid cases, and that puncture of the intestine had been tried as a remedy, naturally with no success. It obviously could have no more effect than the passage of a rectal tube. This condition is also described as occurring in other serious febrile conditions such as lobar pneumonia.

Reviews

THE ART OF PROGNOSIS

Prognosis. Volume 2. (Pp. 410. 10s. 6d. net.) London: The Lancet, Ltd. 1937.

Prognosis, admittedly, is a perplexing chapter in the art of medicine; here particularly must be applied the aphorism, judgement is difficult and even experience fallacious. And yet the art of foreseeing the event is a matter of moment to the repute of the medical practitioner and still more to the prospects, immediate and remote, of the patient. For the most part the successful practice of the art must be self-taught by the doctor himself; no absolute rules can be defined, and balanced statistics are of small value in the presence of the individual sufferer. Manifestly the junior practitioner may expect to learn something from his seniors if only the teaching is effectively presented, and it is a series of successful efforts in this direction that distinguishes the second volume of the *Lancet's* collected articles on prognosis. The subjects considered number some sixty chapters and range from such narrow issues as fractures of the os calcis and breech presentations to the larger questions associated with hypertension, disseminated sclerosis, bronchitis, emphysema, and the rest. Each author has established a title to be heard on the subject on which he writes, and there may be detected throughout the book evidences of a common direction or purpose—namely, the determination, on the basis of clinical studies, to put at the disposal of readers practical and helpful guidance. Many of the contributions are in this respect clinical teaching of the highest order, and even experienced practitioners will find not only interest but also help from their perusal. The volume deserves a cordial welcome and recognition.

CORONARY DISEASE

Diseases of the Coronary Arteries and Cardiac Pain. Edited by Robert M. Levy, M.D. (Pp. 445: 97 figures. 25s. net.) New York: The Macmillan Company; London: Macmillan and Co. Ltd. 1936.

A quarter of a century has passed since the clinical observations of Herrick gave to the medical profession a means of recognizing infarction of the heart. This stimulus evoked a widespread interest in acute ischaemia of the heart muscle, which reached its peak in this country more than a decade later. But the floodlight turned upon the coronary arteries resulted also in a concentrated interest upon other aspects of their pathology. In many European countries and in America innumerable researches were directed to the physiology and anatomy of the coronary vessels and further to the clinical features and treatment of all grades of coronary artery disease. And since the trigger for this discharge of energy was pressed by an American, it is fitting that it should fall to the lot of one of his countrymen to assess the present position of medical knowledge on these matters.

Dr. Robert L. Levy in his treatise has assembled, with the help of authoritative contributors, a survey of this problematic department of medicine. The names of Drs. A. E. Cohn, J. B. Herrick, and C. J. Wiggers, who have formed an advisory editorial committee, indicate the broad philosophic, clinical, and physiological basis upon which the work has been planned. Discussions of the mechanism of the coronary circulation, cardiac pain, and

the clinical features of coronary syndromes are followed by sections on medical and surgical treatment. Although trinitrin undoubtedly benefits many patients and may substantially increase the capacity of an anginal patient for work, there remain actually many whose effort tolerance is so greatly restricted by pain that useful activity becomes impossible.

It is perhaps time for more consideration to be accorded to operative methods of treatment. Dr. J. C. White in the present volume holds that paravertebral alcohol injection of the upper four thoracic sympathetic ganglia is a method that cannot be dangerous and which brings good or fair relief in more than 80 per cent. of cases. The special indications for injection treatment, sympathectomy, the operation of total thyroidectomy, and the methods of supplementing the coronary circulation from neighbouring regions, such as the omentopexy now being developed by O'Shaughnessy in this country, are also discussed.

This book unquestionably takes its place among the important contributions to cardiology at the present day.

DIET AND CANCER

Cancer and Diet. With Facts and Observations on Related Subjects. By Frederick L. Hoffmann, LL.D. (Pp. 767; 15 illustrations. 5 dollars or 22s. 6d.) Baltimore: The Williams and Wilkins Co.; London: Baillière, Tindall and Cox. 1937.

Any medical reader who has kept in touch with the long series of publications relating to cancer issued by Dr. Frederick L. Hoffmann would be ungenerous if he refrained from a tribute of respect to the author, whose latest work, a stout volume of 767 pages, is before us. Dr. Hoffmann set himself two tasks. The first was to collect and summarize the views of others on the relation between dietetic habits and malignant disease and to epitomize current opinion on the processes of metabolism with special reference to malignant disease. The second was to analyse information respecting the physical and physiological characteristics and the dietetic habits of 2,234 patients suffering from cancer and 1,149 controls, "chiefly visitors to hospitals or patients suffering from minor ailments not suggestive of cancerous affections."

Not the least engaging of Dr. Hoffmann's characteristics is candour. He does not claim to have made an exhaustive study of the literature, and he more than once remarks that some of the works he has examined are of too technical a character for it to be possible for him to abstract them. What he *has* abstracted he has summarized clearly; and if it can be said, and said truly, that much which he describes is of little serious value (indeed he remarks that himself) and much he omits is worthy of attention, a medical reader will reflect upon the difficulty of the task. At the lowest, this half of the book will acquaint an intelligent layman with some of the trends of opinion. The other half of the task (beginning at Part IV) is more fully within Dr. Hoffmann's scope. He has tabulated his data in a great variety of ways. It is perhaps a pity that it was not possible to analyse the data of controls as completely as those of patients, for instance, by occupation, because dietetic habits must depend largely upon economic status, but the pains taken are evident. The statistical conclusion reached is that a principal difference between the cancer patients and the controls is the quantitative and qualitative richness of the diets of the former.

"The caloric intake is shown to be excessive in cancer patients who are not in need, in adult life, of so much energy-yielding foods in view of diminished exertion and the almost universal use of mechanical equipment diminishing the amount of bodily exertion generally. The study emphasizes the conclusion that it is not so much a question of any particular type of food product but that all food products seem to be taken in excess, particularly those of high organic content, or energy-yielding foods, beyond the needs of body requirements."

Dr. Hoffmann concludes his work with these words:

"I consider my duty discharged in presenting the facts as I have found them, which lead to the conclusion that overnutrition is common in the case of cancer patients to a remarkable and exceptional degree, and that over-abundant food consumption unquestionably is the underlying cause of the root condition of cancer in modern life."

No doubt this conclusion will not meet with universal acceptance, but the author's patient accumulation of data should receive universal approval.

SOCIAL MOVEMENTS

Aspects of a Changing Social Structure. By Sir Percy Alden, M.A. Sir Halley Stewart Lecture, 1936. (Pp. 190. 4s. 6d. net.) London: G. Allen and Unwin. 1937.

In accordance with the purposes of the Trust under the auspices of which these lectures are delivered, the author in his preface states that his underlying purpose "may be said to be the growing interest of the State in social and industrial problems leading to a wide range of measures designed to give security to the citizen and to the basic industries upon which in the end both citizen and the State depend." This theme is pursued through eight chapters, the first four of which deal with the main social services (with the notable exception of education), and the next three with the organization of industry, with particular relation to coal and to agriculture. A short concluding chapter is in the nature of a summary.

The earlier chapters are those which may be expected to interest medical readers more particularly. They are concerned with the social provision made for the child, for the health of the community, for housing, and for security of the worker in times of unemployment and in old age. They set out relevant facts and figures comprehensively and accurately; but however convenient this may be the result can only be described as commonplace. There is nothing new in the information given, and but little that is very fresh or helpful in the comment. Most thoughtful medical practitioners, social workers, and students of social questions will not find anything with which they are not already familiar. The family doctor, indeed, though not ungrateful for a mild appreciation of his usefulness, will easily detect a not unimportant lack of understanding of the real nature and extent of his functions; nor will any class of official concerned with national health insurance be prepared to endorse the statement that "the approved societies merely pay out and they are in no way concerned as to whether the payment is justifiable." Most of the author's suggestions for improvement are crude, and are not sufficiently developed or expounded to be useful contributions to the discussion. For example, he says: "What is wanted is a periodical health examination from childhood upwards . . . carried out by groups of doctors, some of whom would be specialists." And again: "A properly organized system would make maternity and child welfare officers responsible for the health of children under 5 years of age; school medical officers should take charge from that age onwards until the children leave school, and that after that the panel doctors, or at any rate some of them, might be salaried officers of the local authority and of course be responsible to the Public Health Committee."

These are simple notions, but those with a little more knowledge and experience of the conditions involved will think them impracticable and highly undesirable.

While Sir Percy Alden's book may be enlightening to the uninformed reader in several directions, the mere absence of serious inaccuracy in the statement of facts cannot be regarded as a sufficient substitute for the lack of thoughtful discussion of principles and methods for which the occasion afforded abundant opportunity.

PROCREATION AND BIRTH CONTROL

Marriage and Periodic Abstinence. The Natural Method of Scientific Family Regulation. By J. G. H. Holt, M.D. (Pp. 174. 8s. 6d. net.) London: Longmans Green and Co. 1937.

Voluntary Parenthood. By Edward F. Griffith, M.R.C.S., L.R.C.P. Foreword by Sir Humphry Rolleston, Bt., G.C.V.O. (Pp. 141; illustrated. 5s. net.) London: W. Heinemann. 1937.

To the practitioner unacquainted with recent work concerning the ovulation process, Dr. Holt's small handbook offers most interesting reading. The matter is of great practical importance both to the obstetrician and to the general practitioner. Now that it is possible to place the expected date of ovulation—often even to recognize by symptoms the exact moment of its occurrence—the very best opportunity for conception can be advised to women suffering from sterility. Conversely, the unfertile dates in the menstrual cycle may be calculated and utilized for coitus by couples desirous of avoiding conception.

Dr. Holt's object is to explain the rationale for calculating the days of the menstrual cycle which will constitute the so-called "safe period" for unfertile coitus. Useful as this knowledge undoubtedly is, it is unfortunate that the author is so prejudiced against all other recognized practices of contraception. Possibly it is this attitude which induces him to overlook the impracticability of his advice for use by the average married couple.

Apart from the fact that men and women do not care to regulate their emotional life by dates and schedules, the occurrence of ovulation, besides being impossible to assess during such periods as lactation, prolonged amenorrhoea, or the climacteric, is subject to many variations. Among others the author mentions changes of climate or occupation (holiday time), emotions (such as joy, sorrow, trouble, or fright); over-exertion—even the "worry and fatigue of spring cleaning" has been known to upset the cycle. His advice for such occurrences seems hardly practical enough—"Pass at once into abstinence and seek medical advice."

Dr. Holt gives a good summary of the work done on ovulation by recent investigators, and supports it by excellent material collected from his own case-histories, as well as by reference to historical customs concerning the periodicity of human fecundity. The reader is left with little doubt that valuable light has been shed on the extremely interesting subject of procreation.

It would be impossible at the present day to produce a book on birth control which would be startling or brilliant. The spate of books published on this subject suggests that an audience must still exist, and for this Dr. Griffith's volume offers as good a presentation of the subject as any others we have met. The book is intended for nurses, midwives, and social workers, and could be read by any layman. The author shows a sympathetic understanding of the anxiety with which the working-class mother views the rapid increase of her family. He lays particular emphasis on the prevalence of coitus interruptus, with its train of discordant bodily and psychical symptoms. In his opinion this practice accounts for half the unhappiness in marriage. On such grounds alone it is necessary that better contraceptive knowledge be made generally available.

Interesting statistical data are given to show the prevalence of abortion—either achieved or attempted; the death rate of infants born in quick succession is double that of infants born with a spacing of at least two years. For these reasons also it is the duty of the midwife or accoucheur to see that the patient is instructed in contraceptive technique after childbirth. In addition to such considerations the book gives a few chapters on general biological facts, such as the physiology of conception, secondary sex characteristics, and endocrine functions. The appendix usefully supplies a list of the voluntary and municipal birth control clinics.

Notes on Books

Dr. H. HALDIN-DAVIS has now produced a third edition of his valuable book *Skin Diseases in General Practice* (H. Milford, Oxford University Press, 17s. 6d.). It will be remembered that in this work diseases of the skin are arranged according to their topographical distribution. At the beginning of each chapter appears a list of the eruptions found on that particular part of the body surface of which the chapter treats. Since many common diseases may affect any or every area the three introductory chapters are devoted to diseases which may, on the one hand, be most widely spread or, on the other, extremely limited in their manifestations—septic infections, eczema, and syphilis. Further, references are given from chapter to chapter. This regional plan is very helpful to the practitioner. The indications for treatment are clear and thorough, and there are many illustrations. In order to bring the book up to date Dr. Haldin-Davis has thoroughly revised it and rewritten many passages, with special emphasis on the "elastoplast" treatment of varicose ulcers, the advance in radium treatment for malignant disease of the skin, and the introduction of compounds of gold and other metals in the treatment of lupus erythematosus.

Under the new title of *Tropical Dispensary Handbook* a third edition is now issued of Dr. CLEMENT CHESTERMAN'S *African Dispensary Handbook*. The first was reviewed in these columns on May 10, 1930. The scope of this excellent book has been extended in order to make it useful to workers in all parts of the Tropics. For the information of those unfamiliar with the earlier editions it may be stated that Dr. Chesterman's work was originally compiled from notes of lectures to African medical assistants, and the author's object, which he admirably achieves, is to provide a vade-mecum for the partially trained natives who staff the outlying dispensaries among rural communities. The book is divided into four sections dealing respectively with medical diseases, surgical diseases, pharmacology, and laboratory work. It is published in London by the United Society for Christian Literature at 7s. 6d.

Volume X 1934–5 of the *Transactions of the Bose Research Institute*, Calcutta, describes investigations carried out in different branches of biophysics, in anthropology, and in advanced physics under the direction of Sir JAGADIS BOSE, D.Sc., F.R.S. It consists of twelve chapters, with a brief general introduction by the editor. The paper of most interest to medical readers is that by Mr. H. N. Banerjee on chemical and physiological investigations on the presence of vitamin C in certain substances in plants. The publishers are Longmans, Green and Co., and the price is 18s.

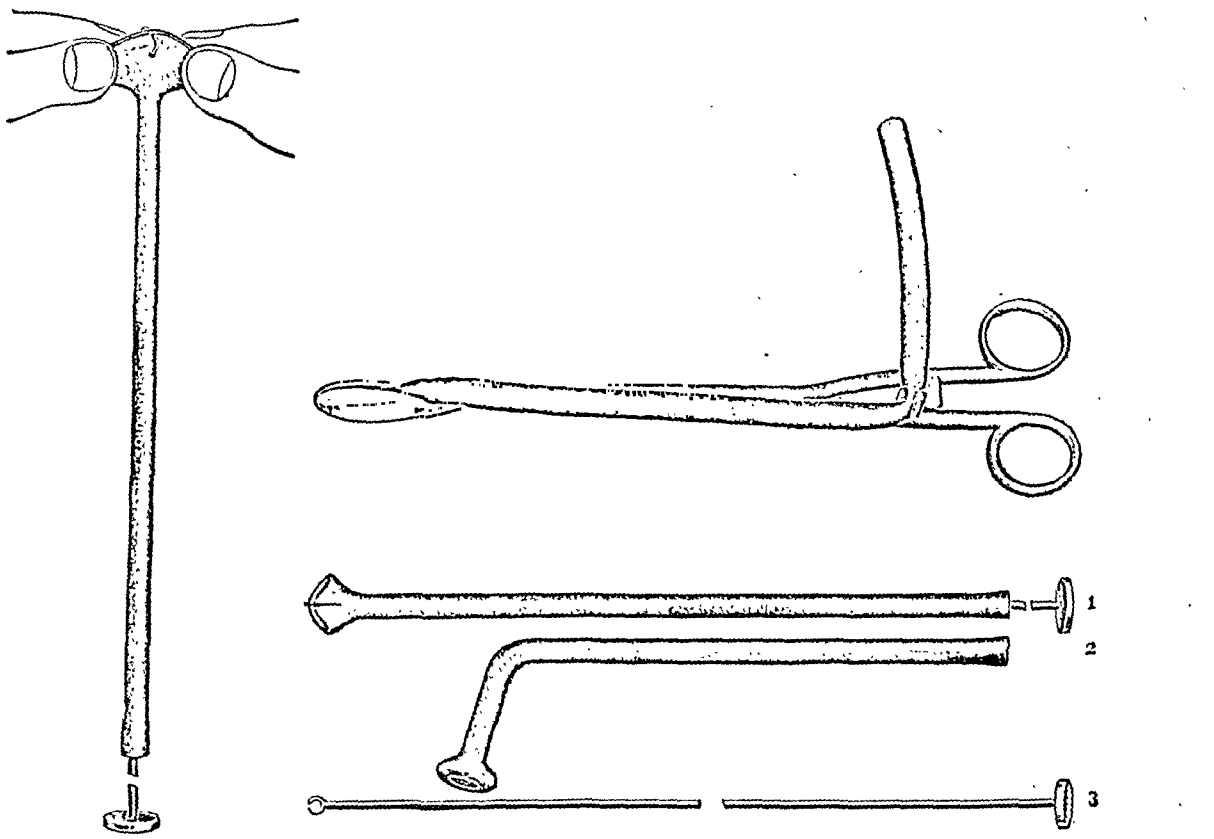
In response to requests for a short description of the principles and technique of graduated muscular contractions Sir MORTON SMART has published a booklet (Oxford University Press, 2s. 6d.). He hopes that the simple explanation here given will assist those who are interested in this means of treating muscles and joints. He insists that it is harmful to muscles—particularly to those already damaged—to cause repeated contractions and relaxations by methods designed "to control the corepiece automatically."

Another annual review is the French *L'Année Médicale Pratique* (Paris: René Lépine, 28 fr.), now in its sixteenth year under the editorship of Dr. CAMILLE LIAN. This ranges from "abcés de fixation" to "vitamine C," and appears to cover the French medical literature in a thoroughly competent manner.

Reprints of papers on research work from the wards and laboratories of the London Hospital during 1936 have been bound together in paper covers, and the volume is obtainable from Messrs. H. K. Lewis and Co. at 7s. 6d.

The London School of Hygiene and Tropical Medicine has published as a pamphlet of twenty-four pages the report of the tenth meeting of the Industrial Advisory Committee of the Ross Institute held on May 28, 1937.

In preparing a fourth edition of his excellent book, *Common Skin Diseases* (H. K. Lewis, 15s. net), Dr. A. C. ROXBURGH has endeavoured to bring it up to date without materially adding to its size. Four pictures have been replaced by better ones and twenty-six have been added.



With the twenty-third edition of Sir WILLIAM HALE-WHITE'S *Materia Medica, Pharmacy, Pharmacology, and Therapeutics,* revised by Dr. A. H. DOUTHWAITE, this ever-popular book (published by J. and A. Churchill at 10s. 6d.) reaches its 115th thousand. It now embodies all the essential changes brought about by the publication of an *Addendum, 1936,* to the *British Pharmacopoeia, 1932.* Besides the new official substances the most important drugs now included are benzedrine, digoxin, ergometrine, mandelic acid, histidine, and protamine insulinate.

Preparations and Appliances

FORCEPS FOR INTRODUCING SUPRAPUBIC TUBE

Mr. H. P. WINSBURY-WHITE, F.R.C.S. (London, W.1), writes:

The instrument illustrated is useful for introducing a self-retaining tube of my own design into a suprapubic vesical fistula; it is not, however, suitable when the fistula is very old-standing, and consequently constricted by a good deal of fibrous tissue. After inserting the forceps into the bladder care should be taken to release the outer end of the tube before the blades are opened. It is interesting to note that in the American pattern of this tube as produced to-day the two small holes on the under surface of the expanded end, which were provided to engage the prongs of the original introducer, have developed into two large openings which are quite unsuitable for their original purpose. In fact, the instrument makers on the other side of the Atlantic appear to have no knowledge of the reason for these two apertures, and refer to them as a provision for extra drainage, a function which they could certainly not fulfil to any appreciable extent. Figures 1, 2, and 3 show the tube and original introducer with the tube ready for insertion.

The most convenient method of inserting the prongs into the two holes which should engage them is to stand the introducer upright, so that it rests on its circular flat end. This leaves the two hands free to manipulate the prongs into their respective places. The original modification of the self-retaining tube was first described in the *Lancet* (1922, **2**, 186). The instrument is made for me by Messrs. Allen and Hanburys of Wigmore Street, London, W.1.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 24 1937

THE PRESIDENTIAL ADDRESS

It is always a pleasure to congratulate the President of the British Medical Association upon the address which he delivers as almost the first official act of his year of office. This can be done quite sincerely because there is never such an address without considerable wisdom and some felicity of expression. It is not invariably the case, however, that these presidential addresses are equally and entirely appropriate either in length or in matter to the particular occasion upon which they are delivered or to the special mixed audience which assembles to hear them. This year it is an added pleasure to recognize that, as in several recent years, the President was successful in holding the attention and interest of his hearers throughout, since both the nature of his subject and his manner of presenting it were attractive not only to the various classes of his medical colleagues but also to that important lay portion of the audience which has to be considered and appealed to on such an occasion. All who heard the address and those who now read it as printed in the opening pages of this issue of the *Journal* will like us to offer congratulations and wish Professor R. J. Johnstone a very successful presidential year.

The main theme of the address was medical education, undergraduate and postgraduate. As a university professor of one of the most important subjects in the medical curriculum, and as an influential member of the General Medical Council, which is charged with the chief responsibility in prescribing that curriculum and has recently given much thought to its revision, the President speaks from practical experience and with the requisite authority. The subject is of prime importance not only to medical practitioners of all kinds but to the general public. To lay administrators, both in central Government Departments and in local health authorities, it seems lately to have presented peculiar attractions, and there is evidence that their judgements and opinions with regard to it are not invariably wise or accurate. Attempts to impose additional requirements upon registered medical practitioners before they shall be allowed to follow their profession in certain directions or within certain fields, in spite of their rights under the Medical Acts, may be wholly mistaken even in respect of the achievement of objects in themselves reasonable and worthy. As the President pointedly said with regard to the health schemes which public authorities are constantly launching one after another: "The administrator has the last word, and while the specialist or whole-time officer is practically immune from criticism the incompetence or carelessness of a few can be alleged as a reason for excluding the whole class of general practitioners from participation in a service." He asks for the rights of all registered medical practitioners to be regarded and conserved, but members of the British Medical Association will be the first to agree that "rights involve responsibilities, and if we are to enjoy the one we must be prepared to the last man to discharge the other."

The methods by which the practitioner may be best equipped for discharging these duties and accepting these responsibilities, and the nature of the opportunities afforded him for so equipping himself, are therefore accepted as matters of supreme importance. Many things can be said, and have been said, on all aspects of this subject, but several points were developed by the President with much clarity and freshness. In a striking passage, contrasting the clinical experience acquired by a trained nurse and that of a medical practitioner, he demonstrated the unique importance of the background of the medical and biological sciences which the medical student laboriously cultivates. "It is the main business of a medical education to provide an adequate background and to teach how it should be used, and the more competently this has been done the more valuable will his clinical experience be to the practitioner." Further, the inculcation of a proper sense of professional responsibility is one of the major objects of medical education: "responsibility to his patients, to his own reputation, and, most important of all, to his own private conscience. The better trained the young graduate the more quickly and more competently does he take up the burden." Again, though the undergraduate must almost of necessity have been taught to think largely like other people, he must also have been encouraged to think for himself, since this, after graduation, should be his chief business. He then "becomes his own teacher and taskmaster." To these ends it is obvious that the skill of the teacher is not only essential but all-important. The President reminds us that "teaching and lecturing are arts that can be learned," and asks, "Would it not be possible that an institution such as the Postgraduate Medical School should give a course in lecturing, and that those who have designs on the teaching posts in our medical schools should be encouraged to take it out?"

The President suggests in conclusion that it is well for the young practitioner to have early in his professional career a period of relative difficulty and struggle, and allows himself just to wonder whether "panel practice is giving him an assured income too soon," and whether it is "taking away the intention to study and to improve the standard of his practice." It is as well that these questions should be asked, for they do hint at a possible danger with a certain type of mind and character; but in general a satisfactory answer can be given to them. No less important than the elements of struggle and emulation is the giving, and even widening, of opportunity, and in a noteworthy sentence the President seeks to assure administrators that "a panel of doctors is just as efficient and reliable as, and gives no more trouble than, a whole-time officer." The whole profession will thank Professor Johnstone for an address which is at once pointed, timely, and wise.

MORE LIGHT—BETTER SIGHT?

Recently, as the result of commercial activity, the slogan "more light—better sight" has become familiar to large numbers of people. In most slogans there is a basis of truth, and where a commercial enterprise concerns medicine it is as well to inquire how much truth is being presented to the public. There has been for some time a drive, originating outside this country, to make the public more "body conscious" in matters of health. How far this is productive of hypochondriacs is a question which would find many and weighty champions on opposing sides. We know that the so-called leisured classes are often the most difficult to cure, whereas as a rule those who have less time to ponder their symptoms respond more readily and completely to treatment. The former rather than the latter class tend to indulge in and support, while it is fashionable, any new health cult, and they will say this is due to their greater erudition and consideration for their bodies. It is doubtful whether they add to the tale of their days by such meticulous care of themselves.

The same is as true of the eyes as of the rest of the body. Thus certain types of over-sensitive or eye-conscious patients require their spectacles to be accurate to an eighth of a dioptre, and inquire as to the best humidity of the room in which reading is to take place; others have difficulty in choosing between lenses of half a dioptre difference and have never heard of humidity. In the Middle Ages it was possible to write and illuminate manuscripts which demanded careful and often very fine work with only rush-lights as an illuminant. Nearer our own time and before the introduction of electricity people could, and did, use their eyes just as much as we do to-day without much difficulty or complaint. Fine work done by the eyes in those days loses nothing in comparison with fine work executed to-day under the most advanced lighting conditions. It is probable, then, that the slogan is in part an outstanding example of good advertising in that it creates a want in the public mind. The difficulty is to determine how much of this want is real and how much is due to suggestion.

The problem of adequate illumination is complicated. The degree of lighting required varies, for example, with the type and quality of work in hand, the error of refraction of the eyes, and the state of health. Other factors, such as the quality and direction of the light, must also be taken into consideration. There is a tendency in the "more light" drive to advise so many foot-candles for reading, so many for sewing, so many for music, etc. Few people are always doing the same work under exactly the same conditions, so that it seems to be unnecessary, except in unusual conditions, to prescribe within narrow limits what illumination is best for any particular patient. Acuity of vision depends upon the contrast in the stimulation of the retinal receptive elements. This obtains more particularly at the edges of the pattern thrown upon the retina. In emmetropia a well-illuminated object with a sharp outline will throw a sharply outlined pattern on the retina. In such a case there is no diffusion of background colour to the pattern, or from the pattern on to the background, and the visual acuity is high. In ametropia and in poor illumination the edge of the retinal pattern is not sharp, and there is interdiffusion between the pattern and the background, resulting in poor vision. This poor vision may be remedied by attention to the focus of the eye and to the illumination. It has been found that the visual acuity, with the focus corrected if need be, rises with increase of illumination up to a certain point. Beyond that point increase of illumination results in a falling off of acuity. The point at which this falling off occurs is difficult of determination, the best illumination depending upon the factors enumerated above.

Experiments made in 1897, which have been accepted as accurate since that date, show that a change in light intensity from 10,000,000 to 1 results in changes of visual acuity of only 20 to 1, and that practically very little increase of acuity is obtained by an illumination of over sixteen foot-candles. The advocates of "more light" are stated to have proved that: (1) Over a wide range of intensity there is a small range at which acuity is at its maximum. Most will agree with this. (2) The maximum acuity occurs at a high intensity.

This does not accord with already accepted data. (3) The range of intensities which produce an observable change in the acuity is large. This does not agree with accepted facts. The chart used for demonstration purposes in the "more light" campaign is shaded from white above to dark grey below. On it are the usual paragraphs in progressively smaller print. The largest print is above on the white background and the smallest below on the dark grey. The smallest print has therefore the least contrast with its background, there being only a difference in light reflection between print and page of about four foot-candles with an illumination of forty foot-candles. The difficulty in the lower region of the card is increased by the glare from the white upper portion when intense illumination is used. The eye is, in such abnormal circumstances, being tested under conditions which rarely obtain in everyday life. The matter has been investigated by the Department for Industrial and Scientific Research, whose publications should be consulted; but before throwing the weight of medical opinion on the side of "more light" careful consideration should be given to the advisability of adding yet one more neurosis to those already complicating the lives of so many of the present generation.

"THE BOOK OF BELFAST"

Belfast has a reputation to sustain in the production of a guide-book for medical visitors. When the British Medical Association paid its first visit to the Ulster capital in 1884 the *Guide to Belfast* written by Dr. Robert Esler and published for the occasion was described editorially in these pages as "the most perfect and handsome" yet issued in connexion with any of the Annual Meetings. To make comparisons is odious, because since then many cities have done excellently in this, as in other evidences of hospitality, but *The Book of Belfast* for the meeting of 1937, edited by Dr. Robert Marshall, will be hard to beat. It is a volume of 160 pages, bound in Irish linen, and is described modestly as an attempt to answer some questions which an interested medical visitor might ask. The answers are given adequately, without being dull even in recounting the history of Belfast's many hospitals. On the cover appears the badge which Dr. R. W. M. Strain has devised for the occasion, and which is reproduced above. It only needs the explanation that the mythological creature, the seahorse gorged with a mural crown, is one of the supporters of the Belfast coat of arms. Dr. Strain reveals himself also as a clever cartographer in a couple of maps, one of Belfast and the other of the six counties, "designed rather for diversion than for direction." On the flyleaf are printed with fine impartiality two judgements upon Ulstermen. One of them is the remark of the late Lord Rosebery, that the race which has been grafted on to the Ulster stem is "without exception, the toughest, the most dominant, the most irresistible race that exists in the universe at this moment." If this sounds a trifle extravagant it is countered at once by John Milton's denunciation that they are "egregious liars and imposters," but the judicial mind was not a characteristic of Milton's genius. Dr. Marshall has been able to draw upon a great deal of local talent and erudition, from the Lord Mayor downwards, and the contributors include several well-known names in Belfast academic and industrial life. After a brief description, not without pride, of the topography of the city and port of Belfast, some forty pages are devoted to the Belfast Medical School and its founders, especially James McDonnell (1763-1845), of whom Malcolm, in his *History of the Royal Hospital*, writes, "No contemporary of any note in Britain was ignorant of his profound learning and distinguished name." Other names are Thomas Andrews, first holder of the chair of surgery in the Royal Belfast Academical Institution (of which the medical school become a department in 1835), and Henry McCormac, first professor of medicine, whose son, Sir William McCormac, was for five years president of the Royal College of Surgeons of England, and whose grandson, Henry McCormac, physician to the skin department of the Middlesex Hospital, is opening Thursday's discussion in the Section of Dermatology. Another chapter of the book describes the beginnings of Queen's College, later the Queen's University, in 1845. There are chapters recording the history of the Ulster Medical Society, founded in 1862, and the formation of the Northern Ireland Branch of the British Medical Association in 1878, followed by the two Annual Meetings in Belfast in 1884 and 1909. From this point the volume follows more closely the ordinary guide-book pattern, describing places of interest to be found in Belfast and its neighbourhood, the local industries, and the facilities for motoring and sport. Professor J. Kaye Charlesworth writes on the geology of Ulster, Mr. J. S. Loughridge on its archaeology, and the Rev. W. F. Marshall explains the accent and idiom which strikes a little strangely on the ear of the visitor from across the Irish Sea. The many illustrations add to the pleasure of the book, giving a better idea of old Belfast and some of its medical worthies. Among reproductions are the cartoons which decorated the programme of a special entertainment organized by Professor Johnson Symington for the delectation of Lord Lister when he visited Queen's to open the new physiology laboratory in 1897. In addition to the figure of a coroneted Lister slaying the dragon, there are lifelike sketches of the two former Belfast Presidents of the British Medical Association, Professor James Cuming and Sir William Whitla, the one as an Egyptian priest and the other as an itinerant musician. Dr. Marshall and all concerned deserve congratulations on a piece of literary work to serve as a memento of a meeting which bids fair at the moment of writing to be one of the most successful and pleasurable of recent years.

ORGANIZATION OF THE VETERINARY PROFESSION FOR CONTROL OF ANIMAL DISEASES

For many years the veterinary profession has been chafing under the rather ineffective and disorganized efforts that have been made by the country to control the diseases of animals generally, and cattle in particular. The National Veterinary Medical Association in 1935 appointed a committee to consider fully the lack of co-ordination of these efforts, their disastrous effects upon the work of the veterinary profession, and the best way of reorganizing their services so that a comprehensive and co-ordinated attack upon animal disease might be instituted. A pamphlet giving the results of these deliberations in full has been published by the Association (36, Gordon Square, W.C.1), and the subject-matter will be found to be particularly apposite to the terms of the Agriculture Bill at present before Parliament. The main recommendations of the profession have already been adopted by the Government, and a centralized veterinary service for the whole of Great Britain, making use of the wide experience of the veterinary practitioner in agricultural districts, is to be inaugurated. The recommendations allow for the development of this service and visualize the gradual establishment of several specialized branches within the comprehensive national service. These various branches are to be directed by a principal veterinary officer, who must be himself directly responsible to the Minister. The report emphasizes that unless the principal veterinary officer has direct access to the Minister, then the status of the professional service will be lowered and there will be grave danger of the scheme making far less headway than is desirable. Up to the present, however, the Government has not seen its way to agree to this increased status which the veterinary profession regards as essential.

EXPERIMENTS ON ANIMALS IN 1936

As was the case last year, the recently issued Home Office return relating to experiments on living animals records an increase in the number of experiments performed. The total figure for 1936 was 822,167, including 36,540 experiments carried out with anaesthetics, and 785,627 experiments comprising inoculations, hypodermic injections, and other proceedings performed without anaesthetics. The aggregate exceeds that of 1935 by 85,451. The return states that in no case had a certificate dispensing entirely with the use of anaesthetics been allowed for any operation more severe than subcutaneous venesection. Except in certain experiments dealing with the efficiency of antiseptics the regulations demand the use of full antiseptic precautions in order that wounds may heal as painlessly as possible. During the year forty-two licensees performed 33,507 experiments in the course of cancer investigation. 6,130 of these were operations requiring anaesthetics; the remainder were almost entirely inoculations into mice or exposure of animals to radiations. Three hundred and twelve licensees performed over 164,000 experiments for Government Departments and other public bodies, including, among many others, the League of Nations, the Commonwealth Government of Australia, and the Crown Agents for the Colonies. In addition more than 323,000 experiments were carried out in the course of the preparation and testing of antitoxic sera and vaccines and for the testing and standardizing of drugs. The inspectors, whose number was increased to three by the appointment of Dr. G. H. Culverwell in May, 1936, made 933 visits to registered places during the year, in most cases without previous notice, and witnessed a number of experiments. Only three cases of irregularity were reported; the offenders were admonished.

HORMONE TREATMENT OF UNDESCENDED TESTES

It is now seven years since Schapiro introduced hormone treatment for undescended testes, and during this period the consensus of opinion, as judged by the published reports, is that the results are encouraging. A. J. Cramer,[1] and W. O. Thompson, A. D. Bevan, and their collaborators,[2] have recently reviewed the published cases, and find that of the total number treated descent occurred in 72 per cent. The results obtained, however, in their own series of cases and the conclusions reached are widely different. Cramer gave twenty cases (ten bilateral and ten unilateral) 100 rat units of antuitrin S twice weekly for varying periods up to two months. Descent of both testes was brought about in seven and of one testis in one of the bilateral cases; of the unilateral cases descent was effected in six. He concluded that hormone treatment is a valuable method of therapy for undescended testes, and that when surgical measures are indicated the results may be enhanced by hormone therapy as an adjunct. Thompson and his collaborators treated eighteen boys between the ages of 1½ to 17 years (three bilateral and fifteen unilateral). The preparation used was follutein, and the dose was usually 200 rat units three times a week for an average of five months. Descent occurred in only four cases: of these three were unilateral, two being of migratory type, and in one of these the testis returned to the inguinal canal when treatment was stopped. In the bilateral case only one testis descended, although treatment was continued for eight months. Seven of the patients in whom descent failed to occur were later operated upon, and in each instance anatomical factors preventing descent were found at operation. They observed, however, that pre-operative administration of gonadotropic substance caused definite stimulation of genital growth, and this seemed to make surgical procedures less difficult. These conflicting results are not easy to reconcile. It is quite probable that many of the successful cases reported in the literature were of the migratory type, which descend spontaneously and which respond easily to hormone treatment. A. D. Bevan is of the opinion that the reports of the power of gonadotropic substance to produce rapid descent in a large percentage of cases are

[1] *Endocrinology*, 1937, 21, 230.
[2] Ibid., p. 220.

exaggerated, but that as he has seen no evidence of injury the method should be given a fair trial; if after six months' hormone therapy no change takes place operation should be performed. The author's impression is that the problem will be thoroughly understood only after more careful attention is given to all the embryological and anatomical factors. Diagnosis and choice of case are important, and yet it is often extremely difficult to be sure clinically whether descent is prevented by mechanical factors. Careful recording of operative findings in all cases in which descent fails to occur after administration of gonadotropic substance will be of considerable value.

VASCULAR CHANGES AFTER SYMPATHECTOMY

Earlier this year[1] we commented on recent experimental work undertaken to elucidate two of the more striking and obscure phenomena observed after sympathectomy in man—namely, the gradual regain of tone of the denervated vessels and the more favourable results of operations on the lower than of those on the upper limb. More recently Ashcroft[2] has published studies of the effects of interrupting at various levels the sympathetic pathways to the upper and lower limbs of the rhesus monkey. Hemisection of the spinal cord above the sympathetic outflow, section of the anterior roots, or division of the preganglionic or of the postganglionic sympathetic fibres is followed within the first few hours by intense vasodilatation in the relevant limb. At this stage the sympathectomized vessels react normally to adrenaline and the temperature of the limb exposed to cold falls no more than is to be expected from increased cooling; the changes at this early stage are independent of the level at which the sympathetic impulses are interrupted. As time elapses the vasodilatation becomes less intense and the denervated vessels begin to react more strongly to constrictor agents. The degree of this enhanced reactivity appears to be more or less inversely proportional to the number of cell stations between the point of intervention and the vessels themselves. Thus, several days after cervico-dorsal ganglionectomy the sympathectomized hand cools considerably when exposed to cold, whereas at a similar stage after division of the sympathetic nerves proximal to the third thoracic ganglion the sympathectomized hand remains warm when the air surrounding it is cooled. Again, the vessels of a hand deprived of its postganglionic fibres constrict to a dose of adrenaline only one-tenth of that required to produce an appreciable vasoconstriction in a normal hand; after preganglionic section the increase in sensitivity to adrenaline is but three times the normal. Increased sensitivity to certain agents after denervation is of fairly general occurrence—for example, of the pupil and the nictitating membrane of the cat to adrenaline. Increased sensitivity to choline esters has been described in voluntary muscle after division of the motor nerve, and has been demonstrated by Ashford in the sympathetic ganglia after preganglionic section. The change presumably occurs in the peripheral structures themselves, but its exact nature remains undecided. The importance of Ashcroft's work is that it demonstrates in the monkey, as previous workers have demonstrated in man and in the rabbit, that regain of tone and gain of reactivity in sympathectomized vessels are greater after post- than after pre-ganglionic section. It therefore emphasizes once more the desirability of preganglionic rather than of postganglionic section as the operation of choice for producing persistent vasodilatation in man.

THE NEW D.P.H. RULES

The resolutions and rules made by the General Medical Council for diplomas and degrees in sanitary science, public health, or State medicine are revised and modified from time to time with a view to the Council being assured that those degrees or diplomas "have been granted under such conditions of education and examination as shall ensure the possession of a distinctively high proficiency, scientific and practical, in all branches of study which concern the public health." In view of the special statutory privileges accorded to the holders of such decrees or diplomas, and of the increasing national importance of the public health service to which these holders may secure admission, the maintenance of a really high standard is necessary and a periodic strengthening of the requirements of both educational course and examination tests is reasonable. The recent revision of the rules has been definitely in this direction, and, as the new rules are to come into operation on October 1, 1938, careful attention should be given to them by all senior medical students and qualified practitioners who contemplate taking the prescribed course and entering the public health service either temporarily or permanently. Several of the changes made are of particular importance. Candidates, as at present, must have possessed a qualification in medicine, surgery, and midwifery for not less than two years; but in future this need not be a registrable qualification, so that persons holding certain Colonial, Dominion, or foreign degrees will not be debarred from obtaining the D.P.H. The diploma, however, cannot be registered apart from some other qualification which has already been entered on the *Register*. The requirement that the candidate shall have attended instruction for a definite number of hours is to be less rigid, the prescribed hours being related to the length of the course and not to the attendance of the student; but such attendance must have been "satisfactory and regular." The subjects of instruction and for both parts of the examination, too, are so stated as to permit a somewhat increased freedom in their treatment and the elimination from them of certain chemical analyses and other matters which experience has proved to be unnecessary; but certain additions have been made in connexion with genetics, mental hygiene, and hospital and mental health services. The most important point for intending candidates to note, however, is that part-time study during the whole of the course is not, after the appointed date, to be recognized. During the twelve months over which the D.P.H. curriculum usually extends there must be a period of "not less than three consecutive calendar

months devoted to the whole-time study" of the subjects necessary for the first part of the examination. This provision may not be accepted without some demur, and it will affect a not inconsiderable number of students; but it should, on the whole, be regarded as a reasonable requirement, tending to make the general course of study for the diploma more thorough and its pursuance more serious than it has occasionally been in the case of some students or institutions in the past.

HEALTH PROBLEMS IN SHANGHAI

The annual report for 1936 of the Public Health Department of the Shanghai Municipal Council is admirably lucid and informative. It states that the incidence of typhoid fever is a source of anxiety to the Department. The continued prevalence of this disease, despite the gradual improvement in sanitation, is attributed to the consumption of fruit and raw vegetables without observing the precautions which are necessary in a land where human excrement is employed in cultivation. Malaria, which has been increasing steadily since 1927, also presents a difficult problem. It is thought that, following the opening of new roads, anophelines infected with the parasites of the malignant form are conveyed by motor traffic from outlying districts into the central areas, which previously had been almost free. As a result anti-malarial measures have been intensified and mechanized attacks with new and deadlier forms of larvicide have been organized. Efforts are also being made to destroy infected mosquitos in houses where malaria has been contracted or cases are being nursed, a procedure which has met with much success in South Africa. With regard to the incidence of malaria during the year, this increased by nearly 50 per cent.; 298 cases were diagnosed, as against 202 in 1935, while *P. falciparum* was found fourteen times, as against seven. Some cases of *P. falciparum* infection were apparently of local origin, though the majority were probably contracted during visits to surrounding areas where malignant tertian malaria is endemic. Only one type of anopheles, *A. hyrcanus* var. *sinensis*, is found in Shanghai and its immediate environs. Information is desirable as to what extent, if any, this insect acts as a vector of *P. falciparum*. In view of the relatively low incidence of malignant tertian compared with benign tertian in Shanghai this insect does not seem to be a potent factor in the spread of the former type of malaria.

JOURNAL OF THE IRISH FREE STATE MEDICAL UNION

It is just two years since negotiations between representatives of the Irish Medical Association and the Irish Committee of the British Medical Association resulted in a plan for the establishment of the Irish Free State Medical Union (I.M.A. and B.M.A.), an autonomous and independent body which would be truly representative of the medical profession in the Irish Free State. Some idea of the success of the Union in its avowed object of "promoting the medical and allied services and maintaining the honour and interests of the medical profession" has been given by the reports of council and other meetings that have appeared in our *Supplement* from time to time. Now to promote this object still further comes the first number, dated July, 1937, of the Union's monthly journal, one of the main duties of which, as stated in the opening editorial, will be to keep members informed of the work the Union is actually doing on their behalf. It will be remembered that the constitution of the Union provides that each member shall receive the *British Medical Journal* each week, and it is therefore emphasized, in the editorial already referred to, that the *British Medical Journal* remains for members the medium through which they will keep abreast of recent developments and progress in medical science and of the medico-political problems that confront the profession in other countries. The *Journal of the I.F.S. Medical Union*, on the other hand, will make public as fully as possible the proceedings of its council and of various committees, report the steps taken to put the claims of the profession before the Free State Government and local authorities, and, as occasion offers, publish articles discussing problems that concern the profession as a whole. It is also hoped to make it a medium for the free expression of opinion. The first issue contains, in addition to the editorial statement of the services our new contemporary hopes to render to members, much that is of importance to medical men in the Irish Free State—for example, some comment on local Garda authorities and the appointment of medical attendants, the retirement of dispensary medical officers, emergency dispensary leave, reports of the annual meeting and of the council meeting on May 13 last, and the terms of appointment to the dispensary service in Northern Ireland. It also contains an account of the National Eye Service as it operates in England, and an appeal for the co-operation of members in the establishment of a similar service in the Irish Free State.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been printed; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who wishes to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Finance Department, British Medical Association House, Tavistock Square, W.C. 1. Those wishing to receive the indexes regularly as published should intimate this.

The proprietors of the *Lancet* have appointed Dr. Egbert Morland as Editor in succession to the late Sir Squire Sprigge. Dr. T. F. Fox and Dr. M. H. Kettle have been appointed Assistant Editors.

The Australasian Medical Congress (British Medical Association) will hold its fifth session at Adelaide from August 23 to 28.

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

RECENT ADVANCES IN ANAESTHESIA

BY

J. BLOMFIELD, O.B.E., M.D.

Anaesthetics as we know them to-day may be said to have started at the period which followed the war, so great an effect did the experience in casualty clearing stations and base hospitals for plastic operations have on the practice of anaesthetists. The contrast between pre-war and post-war anaesthetics is striking. Former practice was almost limited to the administration of ether or chloroform for long operations and of nitrous oxide or ethyl chloride for short ones, in addition to the employment of spinal and regional methods. Prolonged administrations of gas and oxygen were unknown in ordinary practice, and ethylene and cyclopropane had not yet appeared as anaesthetics. To-day, beside these gases, we have vinethene, the various barbiturates used intravenously, several means of basal narcosis, improved methods of spinal and epidural analgesia, and the methods of endotracheal administration.

The defects of both ether and chloroform had long been apparent. The latter was thoroughly well proved to be potentially too dangerous for a routine anaesthetic, and ether, though safe on the table, was guilty of unpleasant as well as risky after-effects. Chloroform is now mostly relegated to certain operations on the upper air passages and to midwifery. Ether is still largely used and is still a valuable anaesthetic, but its chief mode of employment in major surgery is now supplementary. It is given not as the sole or the chief agent but to strengthen when necessary the innocuous nitrous oxide, which has become the chief anaesthetic for long operations. The possibility of using nitrous oxide in this manner is solely due to improvement in the machinery of administration, and for this improvement we have to thank the Americans, and most of all the late E. I. McKesson, who had already in 1910 devised his first gas-and-oxygen machine. During the war the great advantage which nitrous oxide offered over toxic anaesthetics in many critical cases became so obvious that British medical men acting as anaesthetists at the front were led to devise and use machines capable of giving prolonged administration of the gas in a way which had not been possible with the Hewitt type of instrument, up to that time the only gas-and-oxygen machine in common use in Great Britain.

Basal Narcosis

In civil surgery it soon became apparent that there were many major operations, especially abdominal ones, for which the anaesthesia of nitrous oxide unaided was insufficient. War experience had in fact led to an overestimate of the utility of the gas. Nevertheless its advantages as an innocuous and non-poisonous agent remained undisputed, and the object now was to render it more widely efficient. This led to the premedication which is so notable a feature of present-day anaesthetics. It was found that by supplementing atropine, which was the general routine drug given before operation, if any was given at all, by a combination of this with morphine in full doses, or by using omnopon and scopolamine, then the subsequent administration of nitrous oxide and oxygen could be effective, although for abdominal relaxation in difficult subjects considerable quantities of additional ether might still be required. The advent of avertin for the production of what now became known as "basal narcosis" still further extended the possibilities of nitrous oxide. Paraldehyde was similarly administered per rectum. The idea of rendering the patient comfortably drowsy, or actually unconscious, before he left his bed found favour rapidly. The great advantage which such a method has from the psychological standpoint when timid or nervous patients are concerned needs no demonstration.

Later still the production of hypnotic drugs belonging to the barbituric-acid group extended the anaesthetist's choice of preliminary narcotics. Pernocton, much used on the Continent, never found great favour here, but nembutal, both by the mouth and intravenously, is widely employed. Sodium amytal is warmly recommended by some, particularly for obstetrics; evipan intravenously and pentothal are extensively employed to induce unconsciousness before the main anaesthetic is brought in, or, in short operations, as the sole anaesthetic. The rapid action and freedom from all discomfort during induction which are provided by the last two agents have brought them rapid popularity, and it is sometimes overlooked that they cannot be safely regarded as the equals of nitrous oxide from the point of view of innocuousness. The intramuscular injection of evipan to supplement the intravenous injection is likely to lead to local trouble, and at least one fatality due to this procedure has been recorded.

New Inhalational Anaesthetics

While the various drugs and methods to which we have just alluded extended the scope of nitrous oxide and other gases weaker than ether vapour, the latter still remained the routine agent for much major surgery in general practice, and some specialists, valuing the safety on the table and the general efficiency of ether, sought to find out the cause and the means of preventing those unpleasant after-effects which are the great drawback to its general use. It was shown that injection of insulin before and after operation had an effect on the occurrence of toxic symptoms due to ether. It was claimed, moreover, that ether could be made the ideal anaesthetic if due attention were paid to the right bodily state of the patient beforehand, to premedication, the employment of oxygen, routine removal of endotracheal mucus by suction, and the administration of intravenous saline. The patient, according to those who advocate ether in this way, is kept for a week before operation on a meat-free high carbohydrate diet, with abundant vitamins and extra lactose. German authorities claim that with supersaturated ether vapour they abolish most of the deleterious effects of inhalation of this drug, making it unirritating to inhale and not nauseating.

Vinethene, divinyl ether, which was first shown to have anaesthetic powers in 1930, has since proved of great clinical value. Its anaesthetic potency is no less than four times as great as that of ordinary ethylic ether and is greater than that of chloroform. It acts rapidly and has been most valuable in midwifery and as a supplement to nitrous oxide. It is so volatile that it cannot well be given except from some closed form of apparatus, but with this method care has to be taken that there is

sufficient dilution with oxygen or air. Overdose leads to respiratory paralysis, and very long administration may impair the liver.

Cyclopropane, the other recently introduced inhalational anaesthetic, is also a potent gas, the value of which is enhanced by the free dilution with oxygen in association with which it is effective. For this reason it is much employed for the operations of major thoracic surgery. In connexion with cyclopropane mention must be made of the modern technique of carbon-dioxide absorption. For one thing this technique alone renders possible the free use of so expensive an agent as cyclopropane. Its economic value is, however, not the greatest of the advantages of the technique. This lies in the complete control of respiration which the method affords. The administration of carbon dioxide itself in anaesthesia is a modern feature. The physiologists have taught us that it is the natural and most efficient stimulant for the respiratory centre. Consequently it is now commonly employed to hasten induction of anaesthesia by amplifying the breathing and also to facilitate recovery by increasing the rapidity of elimination of the anaesthetic.

While technique is under discussion reference must be made to that which has done more to alter modern methods as compared with their predecessors than any other one factor. This is the introduction of endotracheal anaesthesia. The bugbear of the anaesthetist of the past was most often spasm and congestion of the tongue and upper air passages. Introduction of a catheter through the larynx into the trachea entirely does away with this difficulty. The method, in the words of Magill, whose work in this connexion has been invaluable, "prolongs the trachea" to the mouth. Moreover, this method of introducing anaesthesia has rendered possible some thoracic operations which without it would be barely possible, and has greatly facilitated operations, such as those on the cerebellum, when a prone position of the patient is necessary. Also for operations on the upper abdomen on difficult subjects endotracheal methods are often the best possible solution of the problem. Mention, too, must be made of the long and repeated operations of plastic face surgery, the requirements of which first stimulated the development of endotracheal methods in this country.

Intravenous Methods

Intravenous injection of anaesthetics was tried in many instances about twenty-five years ago. The agents employed were ether, hedonal, and isopral. The first was abandoned because it was found that the large amounts of weak solution needed were excessive and there was danger of waterlogging the lungs. Nor did the other two prove satisfactory enough for them to come into general use, chiefly because of the long unconsciousness after operation. Recently, however, the intravenous method has been reintroduced with much greater success. Good results have been recorded with ethyl alcohol infused along with glucose solution, but the best agents for intravenous anaesthesia are pentothal, evipan, and nembutal. Eunarcon, another barbiturate, gives good anaesthesia for short periods of time. Although the other barbiturates mentioned are suitable for short operations as the sole anaesthetic they are also largely given as precursors to long anaesthesia with other agents; in some hands they are themselves employed as the main anaesthetic for long operations, and for this purpose various instruments have been designed which allow the hollow needle to remain *in situ* in the vein.

To what extent intravenous will supersede inhalational methods it is at present too early to state with confidence, nor have we probably yet arrived at the best possible drug for the purpose. Allusion may be made here to the practice of injecting morphine into the vein, an effective mode of prolonging the anaesthesia of evipan, or other barbiturate, when it is waning.

Spinal Analgesia

One of the chief drawbacks to endothecal methods of analgesia used to be the comparatively short time which could be relied on for effective insensibility. The introduction of percaine, a quinolin salt, a body entirely different chemically from those hitherto employed endothecally, removed this objection. The work of the late Howard Jones put administration of this drug on a scientific basis, and his excellent clinical results are now widely imitated. Some observers have pointed out the importance of warming the solution to body temperature before injecting it. There are still considerable differences of opinion as to the physiology of spinal analgesia and as to the reasonableness or the opposite of producing in this way anaesthesia of the upper portions of the body. It is true that anaesthesia even of the scalp has been successfully obtained, and that tonsils have often been removed with the help of analgesia procured by endothecal injection, but the consensus of opinion is still in favour of limiting spinal methods to regions below the level of the umbilicus as a general rule.

The chief danger of endothecal injection is ascribed to the fall in blood pressure which is associated with it. Controversy still rages over the manner in which this is brought about. Opinion on the whole seems to favour the view that the drop depends on the number of constrictor nerve fibres which are paralysed by the injection, and that the intercostal paralysis and respiratory depression play only a secondary part. Much experimental work has been carried out to determine this question and to ascertain the degree to which absorption of the injected drug takes place into the blood stream, and whether this is in clinical practice a point of real import. It is generally held that respiratory paralysis occurring during endothecal analgesia is never primary through direct action of the drug on the bulb, but is due to secondary stoppage of the breathing through insufficient blood supply owing to excessive fall of blood pressure. Much difference of opinion has been expressed, too, as to the causation of headache, which is sometimes severe after spinal puncture. The treatment most recommended is to keep the patient's head low for twenty-four hours after return to bed. Spinal methods have recently been introduced with striking success into thoracic surgery when lobectomies and other grave intrathoracic operations have to be performed. The injection of ephedrine, of adrenaline, and of icoral is recommended by different authorities as a certain corrective or preventive of fall in blood pressure.

Mention must be made here of a form of spinal analgesia which has not yet been much tried in this country but has had enthusiastic support on the Continent and in America. It is epidural anaesthesia, and depends on injection made, not into the cerebro-spinal fluid as in ordinary spinal analgesia, but into the small layer of loose tissue outside the dura. The method is thus allied to sacral analgesia, when the injection is into the sacral hiatus and again does not involve the cerebro-spinal fluid. This technique has been much used for perineal operations, for which it is excellent.

Splanchnic analgesia—placing a block across the path of impulses passing from the viscera via the coeliac ganglia and the great splanchnic nerves to the central nervous system—has proved of great service in severe operations on the upper abdomen. It is mostly employed in combination with light general anaesthesia, or with basal narcosis, or a field-block of the abdominal wall. This form of anaesthesia has certainly made possible severe and prolonged operations on subjects who could not possibly have survived them otherwise.

Therapeutic Use of Anaesthetics

Several anaesthetics have been of service in a manner entirely different from that for which they were designed. Avertin has been invaluable in the treatment of tetanus, and has been shown to be without deleterious or toxic effect though injected on a large number of occasions at short intervals of time. Evipan has been given with success in the control of delirium tremens, and the barbiturates generally have been found of help in the treatment of mental cases, especially when prolonged narcosis is desired. Finally, it has been maintained that the good results sometimes following the mere opening of the abdomen—for example, for tuberculous peritonitis—are to be attributed not to the operation but to the anaesthetic inhaled, and it has been suggested that repeated inhalations without operation would be a beneficial form of treatment.

No survey of advances in anaesthetics should conclude without allusion to the improvements which have taken place within the last few years in the education and the professional status of anaesthetists. This is well illustrated by the recent institution of a diploma in the subject by the Royal Colleges of Physicians and of Surgeons, this diploma being to a large extent due to the instigation of the Association of Anaesthetists of Great Britain and Ireland, the existence of which body is itself an evidence of the increasing importance which is being given to the practice of anaesthetics as a specialty. Lastly, the first Chair of Anaesthetics in Great Britain has recently been instituted in the University of Oxford through the munificence of Lord Nuffield.

R. D. Evans (*Amer. J. Roentgen.*, March, 1937, p. 368) has found that about 45 per cent. of the total amount of radium stored in the skeleton in cases of chronic radium poisoning gives rise to radon in the expired breath. The amount of radon, and consequently of the radium producing it, can be determined by electrical tests on the expired air. The rest of the radium in the body is determined by the gamma rays produced by its decay product, radium C. Very sensitive quantum-counters, capable of detecting radiation from less than a millionth of a gramme of radium, permit more rapid determination of the radium C gamma rays from a living person than do the usual electroscopes. The author then describes a general method for estimating the extent to which a gamma ray gives off substance in a closed and inaccessible container. The quantum-counters are directly calibrated for rapid measurements of radium C. The rate of the loss of radium by the patient is directly measured by radium analyses of the faeces and urine. In chronic cases 0.005 per cent. a day is eliminated, 91 per cent. of this in the faeces and 9 per cent. in the urine. The mobilization of radium within the body is studied by radon analysis of specimens of alveolar air. Simple gamma-ray examinations of patients will detect chronic radium poisoning five or ten years before any clinical symptoms appear.

RHEUMATIC HEART DISEASE IN THE COUNTY BOROUGH OF DEWSBURY

BY

A. T. ELDER, M.D., D.P.H.

Assistant Medical Officer of Health

The following statistics obtained at a recent survey of school children known to have suffered from cardiac disease may prove of interest. It should be pointed out that the figures refer to the numbers of children whose cardiac debility was of such a degree as to interfere with their normal mode of living to some extent, and is in no way intended to be a reflex of the total incidence of rheumatic disease in Dewsbury. These cases are listed in the school clinic records as heart cases to be examined for the purpose of determining whether they were suitable for attendance at the public elementary school, and whether or not they had recovered sufficiently to lead a normal existence.

The first table shows the classification of these cases according to fitness.

TABLE I

	Males	Females	Total
Number of children fit for public elementary school and for some exercises, but recommended for further observation	4	–	4
Number fit for P.E.S. but excluded from games and exercises	10	6	16
Fit for P.E.S. half-days. Excluded games	–	1	1
Unfit for P.E.S.	1	4	5
At open-air school	1	2	3
			29

Table II shows the number of cases suffering from heart disease directly attributable to rheumatism in some form or other. The other heart cases attributable to such diseases as pneumonia, diphtheria, etc., are classified together as non-rheumatic.

TABLE II

	Males	Females	Total
Heart debility due to rheumatism	12	8	20
Heart debility not due to rheumatism	5	4	9
			29

It is noted, then, that the majority of cases of heart debility are directly the result of rheumatic disease, in the proportion of two to one. In twenty-six of the cases the tonsils were found to be present and enlarged and ragged, or cryptic or otherwise unhealthy. It was ascertained whether or not each case had had the tonsils removed prior, or subsequent, to the onset of heart disease, and the following table is instructive:

TABLE III

	No. of Cases
Tonsils present on examination	26
Tonsils removed	3
Tonsils removed prior to onset of disease	Nil

It will thus be seen that all of these cases had their tonsils intact before the onset of heart disease.

It was next decided to investigate the incidence of these heart cases according to the district in which the patient lived, and it was found that twenty-one lived in the town centre and eight in the outlying districts. Of the twenty-one cases in the town centre fourteen were of rheumatic origin. An analysis of these fourteen cases showed that thirteen of them belonged to the most congested part of the town centre.

The cases were then analysed with a view to discovering what schools contributed most cases, and it was found that seven of these thirteen cases came from the two schools serving the most poverty-stricken and congested area of the town. Another interesting point made out was that only four out of the total of twenty-nine cases lived in the end of the town where are housed almost all the mills, and which might be regarded as the most smoke-laden

part of the town. Table IV shows the incidence of these cases according to the age groups 5 to 9 years and 9 to 13.

TABLE IV. INCIDENCE ACCORDING TO AGE GROUPS

(1) Of all Heart Cases

Age Groups:	Males	Females	Total
5–9 years	4	5	9
9–13 „	11	9	20
			29

(2) Of Rheumatic Heart Cases

Age Groups:	Males	Females	Total
5–9 years	3	3	6
9–13 „	8	6	14
			20

It will be seen from Table IV that six patients suffered from heart trouble in the years immediately following admission to school, and of the fourteen remaining cases it was found that the majority of them gave a history dating back to the age group of 5 to 9 years, and seven of them could be traced back to age 5 or 6.

Commentary

These few results tend to substantiate the theory that rheumatic heart disease in children is a result of infection of the tonsils and that such infection occurs early in the child's school life.

In the majority of cases the rheumatic manifestations were not dramatic, and consisted mainly of indefinite pains of the limbs and joints rather than an obvious attack of rheumatic fever. Of the twenty cases of rheumatic heart disease only five gave a history of rheumatic fever or chorea.

It would appear that the most important examination from the child's point of view is not the one subsequent to school attendance, but one which should be made during the "toddler" stage. Thus an argument can be made out for the routine medical inspection of children attending nursery schools, as it is here that the full effect of preventive removal of tonsils can be gained. The findings certainly suggest this interesting conclusion, although the limited nature of the survey will not allow of a dogmatic statement.

It has been my experience that in too many instances tonsils have been removed merely because they were enlarged, and in too many instances the tonsils were left in spite of symptoms merely because they were not enlarged. The potentiality of the tonsil to lodge the streptococcus and the patient's symptoms, be they ever so indefinite, are of much more significance, and should in no case be neglected.

I have to thank Dr. J. F. Galloway for permission to publish these results.

At the last quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men, with Mr. V. Warren Low, president, in the chair four new members were elected. A donation of £4 15s. had been received from the London Panel Committee, and £2,413 15s. was voted for payment of the half-yearly grants to widows and orphans in receipt of relief. The widow of a member recently deceased applied for relief, and the court voted her a yearly grant of £50 from the ordinary funds and one of £25 from the Brickwell Fund. There are now sixty-one widows in receipt of grants, the largest total since the foundation of the society. A subcommittee was appointed to consider the best method by which to celebrate the 150th anniversary of the foundation of the society next year. The directors desire to bring to the notice of young medical men the great advantages of membership, which is open to any registered medical man who at the time of his election is resident within a twenty-mile radius of Charing Cross. Relief is only granted to widows and orphans of deceased members. Full particulars and terms of subscription may be obtained from the secretary, 11, Chandos Street, Cavendish Square, W.1.

COMMERCE WITHOUT CONSCIENCE

DANGERS OF PATENT MEDICINE ADVERTISING

The first aim of the advertiser is to ensure that his message will be read by the greatest possible number of people of the class to which it is directed. If this object is to be achieved the advertisement must have some quality which will enable it to divert the reader's attention from numerous competing announcements; and of all the devices used for this purpose none is more effective than the topical illustration or headline. This fact is so well known to the advertising profession, that Boat Race Day, for example, would not seem complete without the appearance in the public press of numerous drawings of the contending crews, illustrating more or less appositely a variety of appeals quite unrelated to university athletics. The water that flows between Putney and Mortlake may not immediately suggest a certain modified water prepared in Edinburgh, but there is no doubt that the "Younger Every Day" slogan, if accompanied at the right moment by a picture of Father William at the oars, will attract much wider attention than it would otherwise receive.

Topicality and the Appeal to Fear

But an advertisement, if it is to serve any purpose useful to the advertiser, must not only be read; having been read it must stimulate the reader to action. Now the publicity expert, whether or not he can claim acquaintance with academic psychology, knows that the surest way of influencing the behaviour of men and women is by exciting one or more of those primitive emotions which we have inherited from our subhuman ancestors and which, despite our pride in our exalted rationality, remain the driving forces of our lives, the "springs of conduct." And of human emotions few are so powerful as the emotion of fear. Happy is the advertiser whose prospective clients, puppet-like, can be roused to action by the tugging of this simple string.

The recent bus strike in London produced a crop of patent medicine advertisements in which topicality and the appeal to fear were cunningly combined. The strike was one which closely affected the daily lives of millions of men and women, whose attention was therefore readily captured by any conspicuous reference to the event in the daily newspapers; and these same millions were aware of the strikers' claim that their conditions of work were conducive to nervous and digestive troubles. The manufacturers of nostrums for these disorders were not slow to see in this situation a good opportunity to increase the pulling power of their advertising. There was published, for example, an advertisement in which, below the bold heading "Bus Conductor's Eight Years' Indigestion, Nerves, and Sleeplessness Ended at Last," appeared a picture of the one-time victim (now smiling happily at the reader from the deck of his vehicle) together with an account in his own words of how, after he had "tried indigestion remedies without number," a particular brand of tablets finally cured his "terrible agony." Another announcement, advertising a different specific, began with the startling assertion, credited to a London bus driver, that "three out of every four bus drivers and conductors suffer from gastric trouble." A third, while making no direct reference to the busmen, included a timely dissertation on the danger to the digestive system of the rush of modern life ("Hurried meals, irregular hours, nervous stress and strain"), and went on to explain the prophylactic value of a certain powder

which "neutralizes the acid that is eating into the stomach wall," thus "preventing the development of dangerous ulcers, etc."

"Good Business"

All this is good psychology and good business. If proof be needed it is to be found in the *Statistical Review of Press Advertising*. Reference to this interesting publication reveals the astonishing fact that during 1936 eight firms which advertise remedies for nervous or digestive disorders spent a total sum of nearly a million pounds in the Press alone. During the first three months of the present year the sum spent on Press advertising by the same eight firms amounted to more than £252,000. Continued publicity on this scale can mean only that the goods offered find a very ready market.

The morality of it all is another question. Apart from the doubtful propriety of exploiting for commercial ends the contention of the London busmen that their conditions of work are specially conducive to particular diseases, a contention the justice of which is not here under consideration, grave objections to an advertising campaign of this description readily suggest themselves to the medical mind. Every practising doctor knows how harmful may be the habits of self-diagnosis and self-medication which are encouraged by advertisements of proprietary medicines in the popular press. These habits, in addition to causing in many cases a very unfortunate or even fatal delay in summoning skilled medical assistance, often result in direct physical injury of a serious kind. Recently, for example, attention has been drawn by a medical writer to the risk of alkali poisoning in the indiscriminate consumption of the so-called stomach powders which are widely taken without medical prescription (*British Medical Journal*, November 7, 1936).

Exploitation of Alarm

Perhaps, however, the chief dangers of advertising of the kind here considered are psychological rather than physical. Many of these advertisements are designed to alarm a reader with slight digestive symptoms by suggesting to him that the dreaded acid has already begun its deadly work of "eating into the stomach wall." Dyspepsia and anxiety commonly go together, and although the exact relationship between the two is not clear, it is by no means improbable that this deliberate stimulation of the patient's fear causes a serious aggravation of his physical disorder. Indeed, it is not beyond the bounds of possibility that there are many sufferers from gastric and other complaints whose troubles are primarily due to the fear engendered by such callous and unscrupulous publicity.

This is commerce without conscience, and those engaged in it are not to be moved by any reasonable appeal. It is to be hoped that the day is not far distant when our legislators, who at present seem strangely indifferent to the problem, will provide the protection which the public so urgently needs.

The British Standards Institution has issued a specification for portable chemical fire extinguishers dealing with the foam type and carbon-tetrachloride extinguishers. This specification forms a supplement to the acid-alkali type of portable chemical fire extinguishers; they have been prepared to meet the need felt by users and manufacturers for nationally agreed standards for their equipment. Copies of this British standard (No. 740/1937) may be obtained from the Publications Department, British Standards Institution, 28, Victoria Street, S.W.1, price 2s. 2d. post free.

Reports of Societies

MARRIAGE IN RELATION TO ALCOHOL

At the meeting of the Society for the Study of Inebriety on July 13, with Mr. ARTHUR EVANS in the chair, a paper was read on "Marriage in Relation to Alcohol and Drug Addiction" by Dr. LILIAS BLACKETT JEFFRIES of the New Sussex Hospital for Women and Children, Brighton.

Dr. Jeffries made the remark, which rather surprised her audience, that after somewhat extended research she had come to the conclusion from the authorities she had consulted that marriage and alcohol had nothing in common. The many tragedies in marriage when one of the parties was addicted to alcohol were, of course, well known, but she had endeavoured to study the question objectively, and after going carefully into the conclusions of C. R. Stockard and other investigators on alcohol in its biological aspects she felt that the findings more or less cancelled one another out. Stockard himself rather turned down his experiments in his later writings. She had thought to collect irrefutable evidence of the effect of alcohol on the germ plasm, but this had amounted to nothing.

Alcoholic Parentage

After a brief discussion on the symbolism of alcohol at the marriage feast and the use of alcohol as an aphrodisiac, Dr. Jeffries touched on the question of the effect of alcoholic parentage on the offspring. Karl Pearson's statistical study in 1910 was well known; it had never been repeated in anything like the same massive way. A recent study on the progeny of chronic alcoholics showed that psychosis of many varieties was found to be definitely more frequent in families of chronic alcoholics than in those of sober persons. This upheld the view that alcoholism was one of the manifestations of a defective inheritance. Some writers, however, made a distinction between the offspring of a man before he took to drink and afterwards. The effect on children of alcoholism in the parents was more marked when the defect was on the mother's side. But alcohol was by no means the only racial poison at work, and its effects could not be disentangled from those of syphilis and true inherited defect. Defective lactation was said to be common amongst alcoholic mothers, and also among the daughters of alcoholic fathers in proportion to the degree of their alcoholism. Any such direct effect upon the infant, however, faded into insignificance beside the miserable social results to the children of parents addicted to drink. The most important thing was that the children were deprived of that sense of security on which their outlook in life depended. Lesser degrees of alcoholism also had their effects on family life, which became permeated by uncertainty, fear of the incalculable, sometimes fear of violence. The habit of alcoholism might result from matrimonial troubles, and then in turn aggravate them.

As for legislation affecting marriage and alcoholism, chronic drunkenness was not a ground for divorce in England: it was a ground for judicial separation, which meant that family life was ruined. In Germany drunkards could be legally sterilized, and in two American States—Washington and Ohio—marriage was prohibited to alcoholics. Of course, such laws were easy to evade, but their existence on the statute book helped to create public opinion. As to the therapeutics of marriage in relation to alcohol, she was at a loss to find anything to say. The committee of the League of Nations in its investigations seemed to have touched upon every other aspect of alcoholism save this. In a last effort to say something good about alcohol in relation to matrimony, she could only recall the well-known picture of the old couple toasting one another in sherry on the occasion of their golden

wedding, and Robert Louis Stevenson's advice not to marry a teetotaller or a non-smoker.

Conduct the Criterion for Divorce

Sir ROBERT ARMSTRONG-JONES said that to-day the marriage law in too many instances had ceased to exist except in name, and it was felt that a relaxation of the bonds must be initiated by a change in the law in the interests of the children, the home, and society. Under what conditions might it be justifiable to dissolve a marriage, which was a religious ceremony as well as a legal contract? The present law enacted that the adultery of one of the parties was ground for divorce. Such an act not only defiled the home, but it adulterated the family, and this through conduct which was not only injurious and hurtful to family life, but was detrimental to society. Cruelty, again, was conduct that might mean not only danger to life and limb, but also mental torture. Desertion was a form of cruel conduct which in many instances among the poor would mean starvation for the wife and children, were it not for help from public assistance. All these things—adultery, cruelty, and desertion—implied conduct which was contrary to the teaching of Christ and to the Christian view of marriage as a lifelong union. Conduct, therefore, from whatever cause became the ultimate criterion for divorce. Drink and drug addiction both tended to alter conduct, and the effect of alcohol when taken to excess (and very little affected highly strung persons) was a complete deterioration of the moral life. Small doses of alcohol started a desire and later a morbid craving for stimulants, and the habit of drinking gradually became fixed until inebriety or chronic alcoholism was established. In such case the persons concerned lost all sense of propriety and shame. There should be a way to deal with such conduct for the sake of the children in the home. Already it was punishable to be found drunk in a public place, also to serve drinks to a drunken person, yet such a person could beat his wife and children and drink to excess in his own home with impunity. Another difficult person to deal with was the dipsomaniac, who was quite different from the chronic drunkard or the inebriate. During the craving, although not certified, he was a lunatic. He was a periodic drinker, subject to a sudden, intense, and irresistible impulse to drink, and if this craving were not indulged he might inflict serious injury on himself and others. The same applied to the craving for morphine or opium, for cocaine, and for some other sedatives such as the urea group. Owing to the altered conduct which resulted, it would be possible to deal with these cases under the more general title of cruelty, and so include alcohol and drug addiction under the section dealing with cruelty or insanity.

Sexual Difficulties and Alcohol

Dr. A. E. A. CARVER said that in an institution for inebriates, on investigating the origins of the drink habit, marriage and drink were often found to be very closely associated. Sexual difficulties and alcohol went together. Alcohol helped a person temporarily and fictitiously out of those difficulties; it also indirectly increased them, and alcoholic indulgence might even come to take the place of sexuality, so that a person drank instead of behaving in the normal sexual way. The effect upon the children when either parent was alcoholic was simply disastrous. The children did not know where they were. Very often there was marital cruelty which made the children take sides for or against a parent. The only good thing that followed from a drunken parentage was the frequency with which the children became rabid teetotallers.

Other speakers, lay and medical, gave their opinions briefly on the subject, and the Sister Superior of Spelthorne St. Mary mentioned that in the home for inebriates of which she was in charge the drug addicts were nearly always unmarried women, while the alcoholics were almost invariably married and attributed their alcoholism to married unhappiness.

SCOTLAND

Cost of Chronic Sickness

At the annual meeting at Largs of the Scottish Association of Approved Societies Miss Muriel Ritson, Controller in the Department of Health, said that insured persons continually sick over the year accounted for more than half of the total sickness among insured persons and for over 40 per cent. of the expenditure on sickness and disablement benefits. The influenza epidemic early in the year had cost £200,000. The lines of development which seemed likely to reduce the bill for sickness seemed to be that young people should be given in pre-insurance days every possible aid to the maintenance of health. The total number of periods of incapacity for the past year reached the exceptional figure of 480,000, which was 28 per cent. above the average of the six years 1930-6 and 27 per cent. above the figure for the previous year. The number of cases of sickness other than influenza had increased from 305,000 in 1930–1 to 357,000 in 1936–7, and there was evidence of an increasing amount of illness of the more persistent kind. These chronic cases had accounted for more than one and a half million weeks of sickness. The speaker mentioned a Danish scheme which included a system of notification of persons under 30 with disabilities which would cause considerable permanent loss of working capacity, and training was provided for these. At first it had been difficult to persuade employers to take on such persons, but this difficulty had been overcome. The Department of Health proposed to begin in September an inquiry into the cause and treatment of illnesses lasting over thirteen weeks, with the object of finding out the causes of long illnesses and the extent to which measures of rehabilitation were required in this country. Mr. T. W. Wallace, who presided at the meeting, expressed his belief that the increase of sickness was partly due to an increased willingness to claim benefit and partly to an inclination to regard as incapacitating a degree of illness which before 1913 would not have justified abstention from work. He hoped that the fitness campaign would bring an improvement which ordinary medicine and dentistry, combined with careful administration, seemed powerless to effect.

Veterinary Education

At the annual prize distribution of the Royal (Dick) Veterinary College, Edinburgh, Sir Thomas Hudson Beare, who presided, said that the number of students was increasing year by year, so that their present buildings were overcrowded. The Development Commissioners had made a grant of £20,000 provided another £20,000 was raised by public subscription. Sufficient had now been received to justify the board of management in having plans prepared for the first extension, and it was hoped these would be acceptable to the Treasury. Speaking of the proposed scheme for centralization of veterinary services, he said that the College was directly concerned in the proposal. London was a long distance away, and local considerations were apt to be forgotten. If this was merely an administrative question it did not matter greatly, but if it included an idea that research into animal diseases should be concentrated in London and cold-shouldered in Scotland he would be very strongly opposed to it. In a higher institution like the College, research and teaching must go on side by side. Principal Charnock Bradley said that whatever development took place the production of efficient practitioners was of primary importance. Professor W. T. Ritchie, who presented the prizes, said that the students might be justly

proud of this institution, which owed its inception 114 years ago to the genius and patriotism of a private individual. The influence of John Barclay, a distinguished anatomist early in the nineteenth century, had determined William Dick to become a veterinary surgeon and to found a veterinary hospital, and in 1823 he had established under the auspices of the Highland Society of Scotland the veterinary school which still bore his name. The veterinary art differed in some respects from that of the medical practitioner, but the science which inspired the two professions was the same. Both had to know the fundamental principles of dietetics, pathological processes, and the preservation of health. A vast amount of disease affected man as well as the lower animals, and all investigations and discoveries about these diseases were of mutual benefit to medical and veterinary science. It was possible that new discoveries regarding distemper might have a bearing on influenza. Within recent years there had been a rapid expansion of knowledge on every phase of biological science, and veterinary education was undergoing reform in conformity with modern standards, so that the curriculum had been extended to five years. The college buildings, which afforded adequate accommodation twenty years ago, now needed to be extended to meet the requirements of teaching and research, and it was a good omen that the Treasury was becoming increasingly sympathetic to the endowment of research in animal diseases.

Princess Margaret Rose Hospital

At the annual meeting of subscribers to the Princess Margaret Rose Hospital for Crippled Children, Edinburgh, on July 9 the Earl of Home, who presided, announced a gift of £8,000 from Lord Nuffield as a contribution towards the £10,000 required for an extension to the hospital. A sum of £700 from the Scottish Women's Rural Institutes was also mentioned: this had been collected as a gift to the Queen in commemoration of the coronation year, and had been passed on by Her Majesty for the benefit of the funds of the hospital. The annual report submitted by Lady Findlay indicated the rapid growth of this hospital, which was opened five years ago for thirty patients and which now contained 100 beds, a number that proved to be insufficient. The hospital was the pioneer of orthopaedic work for children in Scotland, and served the ten counties in the south-eastern area of the country. Last year 236 children had been treated, and there had now passed through the hospital in the five years of its existence 565 patients. In addition, clinics in Edinburgh and the county areas were regularly visited, and close touch was maintained with the local authorities, whose medical officers now realized the great value of the clinic services. The financial position of the hospital continued to improve, and it had been found possible within the last few months to pay off a temporary loan of £3,000 granted by the Scottish branch of the Red Cross Society. Expenses for the past year had amounted to £11,229, and after setting against these the maintenance charges received from local authorities, etc., and subscriptions amounting to £2,008, the deficiency to be carried forward was £863. As the hospital increased in size and more charges for maintenance were received the expenses per head would tend to diminish. Mr. W. A. Cochrane said it was now possible to claim that 75 per cent. of all crippled children could be benefited sufficiently to enable them to earn their living. Many of them were completely cured, and for a certain proportion who had a serious permanent physical handicap a system of vocational training effected sufficient rehabilitation. Local clinics connected with the hospital now numbered twenty, and were an essential link in the scheme for getting the patient early and providing preventive out-patient care. The hospital needed many more, and the importance of the preventive aspect of this work should be emphasized. The present national drive to improve physical education was really a national orthopaedic system. After the meeting a garden party was held in the grounds, and the audience of about 500 people inspected the new massage department, swimming pool, and wards of the hospital.

St. Andrews Ambulance Association

At the annual meeting in Glasgow on July 2 of the St. Andrews Ambulance Association it was intimated that the King and Queen had granted their patronage to the association. Sir John Stirling Maxwell, who presided, said that during the year the headquarters staff of this association had attended 1,611 accidents in which motor vehicles had been involved. There had been a great increase in the number of cases to receive attention all over the country; 47,422 calls had been made upon the association's wagons, of which 10,987 were cases of accident. An aeroplane ambulance service instituted in 1933 was doing useful work, and during the year forty-two patients had been brought from remote islands to Glasgow for urgent treatment. There could be no doubt that many lives had been saved by this rapid transport, and it had in a sense completely transformed the conditions of life in the outlying islands of Scotland. This association was one of the bodies to which the Government had entrusted the duty of instructing the public in air raid precautions, and during the year over 3,000 members had received such instruction. Colonel D. J. Mackintosh, speaking of the steady increase of the association's work, said that in 1912 its income had been £4,000 and in 1937 it had increased to £15,500, but further subscriptions and donations were required to support the work. Subscriptions from employees had in the past year increased by over £400.

Registrar-General for Scotland

The Secretary for Scotland has appointed Mr. James Gray Kyd to be Registrar-General for Scotland in the room of Mr. A. Froude, retired. Mr. Kyd entered the Civil Service in 1912 as actuary of the National Health Insurance Joint Committee in charge of the branch office in Dublin, and afterwards in Edinburgh. He has been a principal actuary in the Government Actuary's Department in London since 1926, and secretary to that department since 1932. He will take up his new appointment on September 1.

ENGLAND AND WALES

The King's Fund

At the annual meeting of the President and General Council of King Edward's Hospital Fund for London the Duke of Kent read an appreciative message from the King and mentioned the first appearance in the balance sheet of a full year's income from the gift of £20,000 by King George V. He expressed the hope that in the current year the deficit on last year's working would be wiped out and the Fund return to its usual proud position of paying its way out of current revenue. The financial summary for the year showed that the ordinary distribution had remained unchanged at £300,000, the total to which it was raised during the crisis of 1932, but there had been added for the first time a distribution of £2,000 in respect of the work done for hospital out-patients by district nursing associations. The number of hospitals receiving grants was 146 as compared with 145 in 1935, and the number of convalescent homes aided was fifty-six—an increase of two over the total for the previous year. During the last ten years a total sum of £3,256,088 has been allocated to hospitals and convalescent homes. In 1936 a further gift of £10,000 for its radium work was received by the Fund and used to increase the stock of

radium held to 17 grammes as well as to facilitate various schemes for enhancing the usefulness of this method of treatment. The League of Mercy contributed £10,000. Expenses during 1936 amounted to £16,405, less than a quarter of which was expenditure on the collection of money and on propaganda for the King's Fund and the hospitals. A fresh series of illustrated lectures to schools and other audiences, followed by visits to hospitals, was organized during the year under review; drawing-room meetings were held, and there was a display of modern hospital equipment at the Ideal Home Exhibition. Through the generosity of Lord Wakefield the Fund was enabled to undertake the preparation of a new and more ambitious film, which it is believed will have much propaganda value. The Management Committee of the Fund issued a revised memorandum on fire precautions in 1936 following those previously published in 1907 and 1926. The special needs of the Fund at the moment include additional financial assistance to meet the deficit, which has amounted to about £7,000 in each of the last two years, to increase the annual distribution to meet the greater needs of the hospitals consequent largely on the rise in prices and the advances in medical science, and to provide more substantial assistance to schemes for bringing and keeping hospital buildings and equipment up to the constantly rising standards. It is noted in the report of the Revenue Committee of the Fund that the ordinary income of the hospitals rose by about £152,000, but that this did not keep pace with the rise in expenditure, which was estimated at £184,000. The main financial problem now seems to be the increasing costs of maintenance, due largely to the present rise in prices, to better conditions for nurses (including shorter hours of work), and to the cost of new scientific methods of treatment. The most recent memorandum (issued last week) dealt with the reduction of waiting in out-patient departments between the time when the patients arrive and when they meet the medical officers.

The Merseyside Hospitals Council

The Merseyside Hospitals Council (Merseyside for this purpose meaning Liverpool, Birkenhead, Bootle, and Wallasey) has now completed ten years' work. It has brought together the management boards and honorary medical staffs of the voluntary hospitals in its area, and such bodies as organized labour, employers' associations, and the churches in hospital support. The income of its predecessors, the Liverpool Hospital Saturday and Sunday Funds, before the Council was established was some £25,000 a year. In 1936 the Council's income was £180,000. About 90 per cent. of this income is derived from the "penny in the pound" fund, which increased by some £14,000 during the last year. This increase is partly attributable to steps that have been taken by the Council to improve the machinery of extension, particularly through a regular system of surveying the 6,500 contributing establishments operating the fund to make sure that facilities are provided for the clerical, junior, casual, and seasonal employees and pensioned persons to contribute. The cost of collection, including propaganda, of the "penny in the pound" is 9 per cent. of the revenue. There are over 300,000 contributors, and in 5,000 of the contributing establishments, being 77 per cent. of the whole, the employers add one-third to the employees' contributions, the amount so added last year being over £29,000. The Guild of Undergraduates of the University devotes much time and energy each year to an annual collection for the hospitals, and as a result a further £6,000 was made avaiable for distribution by the Council. During the last eight years, thanks to the operation of the Council, the associated hospitals have been able to add £140,000 to their funds, and more than half a million has been spent on maintaining, extending, and improving hospital buildings and equipment. Even so the hospitals still have to use free legacies to meet current expenditure. The Council's main purpose is the maintenance of the voluntary hospitals, but it works in co-operation with the municipal hospitals, and has agreed to an increased grant to the corporation for services rendered to contributors in those institutions, in return for which the corporation refrains from assessing the contributors who enter a municipal hospital. Lord Cozens-Hardy, who has been chairman of the Council since its inception, has felt compelled to resign by reason of the many public and business claims upon his time, and Mr. W. Sutcliffe Rhodes, chairman of the David Lewis Northern Hospital, has been elected to succeed him.

Health of Manchester School Children

Dr. Henry Herd, school medical officer for Manchester, in his annual report for 1936 draws attention to the recent appointment of a school aurist and the establishment of two classes for partially sighted children. All children inspected during the year were assessed by the medical officers in regard to their state of nutrition. Dr. Herd, while indicating the difficulties and fallacies inherent in such assessment, produces figures which show that on the whole the nutritional condition of the older children was better than that of the younger, and that actually the total numbers classed as malnourished were small. In the special inquiry into these cases of malnutrition the average expenditure on food in the families concerned was investigated. The tabular results of this inquiry seem to substantiate Sir John Orr's statement that only when the amount expended on food reaches about 10s. a week per head is the feeding of a family likely to be satisfactory. Dr. Herd suggests that apart from supplementing inadequate food intake in these cases much could be done by educating the public in the values of the various foodstuffs, and by educating mothers in the art of cookery.

FRANCE

[FROM OUR CORRESPONDENT IN PARIS]

Venereal Disease Statistics

The French Ministry of Public Health has issued some disquieting statistics concerning syphilis in connexion with the Bill for the reform of the campaign against venereal disease. It is estimated that syphilis is responsible for 40 per cent. of the cases in hospitals for chronic diseases, for 10 per cent. of the general mortality, for 75 per cent. of the deaths due to congenital debility, for 50 per cent. of sudden deaths and deaths due to disease of the nervous and cardiovascular systems, and for 33 per cent. of the deaths due to disease of the renal and digestive systems. There is, however, matter for rejoicing as well as dismay. The number of anti-venereal services has increased from forty in 1916 to 1,821 in 1936, and the number of cases of primary syphilis in the army has fallen from twenty-one per 1,000 in 1917 to less than two per 1,000 for some years past. There has also been such a remarkable decline in the rate of stillbirths and deaths due to congenital debility and malformation during the first year of life since 1919 that an annual gain of over 20,000 lives can at present be claimed in connexion with this change.

Declining Numbers of Foreign Medical Students

Professor Hartmann, late president of the French Academy of Medicine and the very active President of l'Association pour le Dévelopment des Relations Médicales entre la France et les Pays Étrangers, has lately drawn attention to the very significant decline in the number of foreign medical students registered by the Paris Faculty of Medicine. The peak was reached in 1929, when 293 such students were registered. The corresponding figures for 1934, 1935, and 1936 were 94, 71, and 31 respectively. On the other hand, the number of

French medical students registering in Paris is rising. This ebbing of the foreign tide is, in Professor Hartmann's opinion, a sad phenomenon, not least because it may mark a decline in the influence of the Paris Faculty of Medicine in other countries than France. He is sceptical as to a reversal in the near future of this movement, whose causes, he considers, are numerous. The most important is probably the world crisis with its monetary restrictions. The agitation against foreign medical students, rather hectic only a short time ago, and conducted with all the impetuosity of nationalist youth, has also played its part; and the stranger within the gates has not been slow to scent the antagonism against him. Then there are the growing counter-attractions of magnificent new hospitals and laboratories in countries other than France, not least in the South American countries.

The French Birth Rate

The subject discussed by the Assises de Médecine last March was the French birth rate, and the conclusions to which this meeting came were of such interest and importance that a summary of them was presented to the Academy of Medicine on June 8 by Dr. H. Godlewski, the secretary of the Assise. Though nothing startlingly new emerged from this discussion, it proved instructive on account of the emphasis given to certain elements of the problem. It was generally agreed that the two most important factors responsible for the decline in the birth rate are birth control or voluntary restriction and induced or voluntary abortion, which in some parts of France has become such a scourge that it is held responsible for "the failure of a quarter of the births." In more general terms the decline in the birth rate was traced to the "penetration of modern animation" into the community —an apt if vague formula. Dr. Godlewski's report was followed by a discussion which ended in the appointment by the Academy of a commission for the study of the means whereby the moral standards as they affect the birth rate may be raised for the benefit of the country. This commission was appointed in spite of certain criticisms by those who doubted the ability of the Academy of Medicine to deal with the moral aspects of the problem. These latter may be and, indeed, probably are its most important aspects, and if 1,034,000 infants were born in France in 1868 and only 638,000 in 1935, this remarkable decline would seem largely to be due to the change in the mothers from timid modesty to bored and brazen indifference with regard to their yet unborn progeny. As Dr. A. Siredey remarked, one could, a generation ago, draw a confession of induced abortion out of a woman only with the greatest difficulty; to-day women think nothing of volunteering such information to any doctor who will listen to them.

Surgeon and Prophet

Dr. G. Lavalée has lately dug out of obscurity the prophetic musings of a surgeon of Montpellier nearly one hundred years ago. He was Professor Lallemant, whose career was so distinguished that in 1843 he was a candidate for membership of the Institut de France. Setting out for Paris in mid-winter to sustain his candidature by appropriate lobbying, he was caught in a snowstorm, and for three days had to kick his heels in a small farm. Having cornered all the available white paper in the locality, he set up his study in a stable and proceeded to cast the horoscope of the world during the next hundred years. This precursor of H. G. Wells foresaw the time when ships would have no sails, masts, or funnels, but would race along at an incredible speed given them by screws. The Suez and Panama Canals were visualized as realities, as was the admission of women to all the educational facilities and professional careers at that time open only to men. Scholarships would be given to the most promising students, and public appointments would depend on competitive examinations. Emancipation of the Press, separation of State and Church, and universal suffrage were also foreseen. In the political world the storm-bound professional surgeon and amateur crystal-gazer anticipated the liberation of Italy and the unification of the German Empire. The prophet who scores so many bull's-eyes at long range deserves all honour, not merely in his own country, and he should be listened to with all due respect and humility when he speaks of the future of a neighbouring country. Professor Lallemant prophesied decadence for England, "the fate awaiting all those peoples who are commercial to the exclusion of all else."

BRITISH EMPIRE CANCER CAMPAIGN

In the absence of Viscount Hailsham, Lord Horder presided at the last quarterly meeting of the Grand Council of the British Empire Cancer Campaign held at the new offices, 11, Grosvenor Crescent, S.W.

It was reported that the first meeting of the newly formed Co-ordinating Committee, set up to ensure the closest co-operation in cancer research and appeal administration between headquarters and its provincial autonomous branches, with laboratory centres of research, had been held in London on July 7. The meeting had been attended by representatives of the Yorkshire Branch, the Birmingham Branch, the Lancashire, Cheshire, and North Wales Branch, and the North of England Branch. It had been decided that future meetings of the committee should be held in the provincial centres, the first being at the Yorkshire centre in Leeds.

On the recommendation of the Scientific Advisory Committee the following grants were approved: £500 to Dr. P. M. F. Bishop at Guy's Hospital for the expenses for one year of certain investigations in regard to endocrine therapy in relation to cancer; £250 to Professor G. I. Finch at the Imperial College of Science and Technology for the expenses of an investigation into the nature and structure of carcinogenic compounds; and £160 to Dr. P. R. Peacock at the Glasgow Royal Cancer Hospital for the purchase of special apparatus for the continuation of his cancer research. On the recommendation of the Joint Committee of the Campaign and of Mount Vernon Hospital, Dr. G. Cranston Fairchild was reappointed the William Morris Research Fellow in Radiology at that hospital for a further period of one year. The William Morris Research Fellowship was established five years ago by a gift of £25,000 from Lord Nuffield.

Grand Council received a detailed report of the activities of its Central Propaganda Committee, and voted a further grant for the year 1937-8 for the extension of the scheme for free educational lectures to the public in the counties of Bedfordshire, Berkshire, Buckinghamshire, Cambridgeshire, Essex, Hampshire, Hertfordshire, Huntingdonshire, Kent, Norfolk, Northamptonshire, Oxfordshire, Suffolk, Surrey, and Sussex.

On the nomination of the Middlesex Hospital Professor J. McIntosh, M.D., director of the Bland-Sutton Institute of Pathology of that hospital, was elected one of its representatives on the Grand Council.

The date of the annual general meeting of the Campaign, to be held at the House of Lords, has been changed to Tuesday November 30, when H.R.H. the Duke of Gloucester, the new president, will take the chair.

In May, 1933, the establishment was announced of a scheme of research fellowships in accordance with a direction in the will of the first Viscount Leverhulme that the income arising from part of his estate should be devoted to the granting of scholarships for research and education. The list of fellowships and grants for research in 1937 has now been issued by the secretary, Leverhulme Research Fellowships, Union House, St. Martin's-le-Grand, London, E.C.1. The recipients of grants include D. Elliot Dickson, M.D., F.R.C.S.Ed., of Lochgelly, Fife, for an investigation of occupational morbidity in coal miners in Scotland.

Correspondence

When to Operate in Appendicitis

SIR,—The following summary of treatment of acute appendicitis may be helpful to your correspondent Dr. H. Hepburn (*Journal*, July 3, p. 34). All surgeons agree that the sooner an appendix in the early stages of inflammation is removed the better, but there is still some disagreement regarding cases of more than thirty-six or forty-eight hours' duration, in which there is an indefinite mass (local peritonitis) or a circumscribed swelling (abscess). Following the principles enunciated by Ochsner and Sherren, I have always advocated that expectant treatment should be adopted in these cases, with the following results:

1. Expectations are realized and inflammation resolves. The appendix is removed three months later, and contrary to expectations the freedom from adhesions is remarkable. In about 65 per cent. of cases inflammation subsides, and the subsequent operation is clean and simple and the wound heals soundly.

2. In about 25 per cent. of cases an abscess forms, if one is not already present. This is no cause for alarm, as it indicates resistance on the part of the patient, and that adhesions have arrested the spread of infection. Expectant treatment is still adopted, but simple drainage may be advisable for two reasons: (*a*) Increase in size of the abscess. Although an abscess will usually rupture into the bowel, the possibility of leakage into the peritoneal cavity cannot be overlooked. (*b*) Slow absorption, as toxaemia is liable to cause visceral degeneration. After simple drainage or absorption of an abscess three months are allowed to elapse before the appendix is removed.

3. In about 10 per cent. of cases expectant treatment must be abandoned on account of exacerbations of pain, increase of local tenderness and rigidity, or elevation of pulse and temperature.

Large numbers of statistics from various sources show that the mortality of cases with localized peritonitis or abscess subjected to immediate operation is about 6 per cent., whereas with adequate expectant treatment the mortality is 3 per cent. Moreover, with expectant treatment complications such as cellulitis of the abdominal wall, secondary abscesses, faecal fistula, etc., are reduced by more than 50 per cent.

With regard to the case quoted by Dr. Hepburn, as it was a six-day appendix with a localized swelling I feel that by adopting expectant treatment the medical officer in the hospital was acting in the best interests of the patient. At the same time the "trenchant comments . . . of surgeons on . . . doctors" who delay in sending patients to hospital are completely justified. Efficient expectant treatment can only be carried out in a nursing home or hospital where the patient is under constant supervision of the surgeon, who can then immediately operate if any untoward features become evident.—I am, etc.,

London, W. 1, July 14. R. J. MCNEILL LOVE.

Technique in Knee-joint Operations

SIR,—The value of aseptic technique as practised by Lane was probably his greatest contribution to surgery, but Mr. Blundell Bankart (*Journal*, July 17, p. 136) must know that even in his hands it was not infallible. So far as I am concerned we are agreed that the deeper layers of the skin may harbour organisms, and that these are in dangerous proximity to the field of operation when the skin has been incised. I personally believe that there is less chance of infection of the wound if the cut edges of the skin are immediately painted with iodine. My friend Mr. Blundell Bankart prefers to rely on the clipping of towels over the margins of the wound. He does not seem to be aware that organisms may have other methods of progression than what he describes as my "fantastic notion of micro-organisms jumping through a sterile towel." Mr. Bankart and I know that our results are very much the same, and it may be that a combination of both methods is the best solution, but in any case I am sure that he is unwise to preach the doctrine that because great advances in surgical technique have been made since the days of Lister none are possible since the days of Lane.—I am, etc.,

Birmingham, July 19. NAUGHTON DUNN.

Insulin Hypoglycaemia in the Tuberculous Diabetic

SIR,—In 1925 (May 30, p. 1004) you were good enough to publish a note of mine on the subject of hypoglycaemia in which I described a fatal case in a young diabetic who was also suffering from pulmonary tuberculosis. This case was also quoted by Wauchope (*Quart. J. Med.*, January, 1933) in a critical review of the condition, in which he also mentions another case and comments on the smallness of the dose of insulin and the relatively long interval between suspension and the fatal attack, which interval was two days in my first case.

In my clinic at Liverpool this has happened again. A man of 25 attended from September, 1933, to April, 1934, during which time his weight increased by 11 lb. and, when he ceased to come, he was taking 20 units of insulin daily; his carbohydrate intake was uncertain as he was unreliable about his food. He was not seen again until July 1, 1937, when he was admitted into hospital at 9 a.m., emaciated and with glycosuria. An *x*-ray examination showed diffuse pulmonary tuberculosis, and insulin was withheld until the evening, when 10 units were given just before a good meal. Nevertheless, he died at 9.30 p.m. in hypoglycaemic convulsions. The one blood examination that was possible showed 107 milligrammes of sugar and 39 milligrammes of urea per 100 *c.cm.* A *post-mortem examination* was made. Protein shock has been suggested as a cause of this hypersensitiveness, but I should be glad of the views and experiences of others who are interested in the diabetic.—I am, etc.,

Liverpool, 1, July 12. H. S. PEMBERTON.

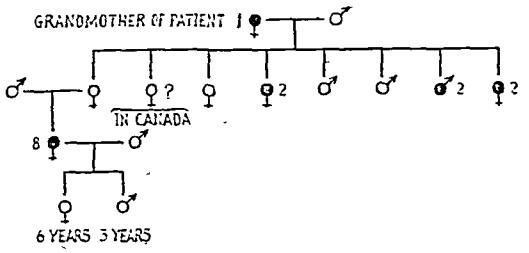
Chronic Monocytic Leukaemia

SIR,—I have read with interest Dr. G. Stewart Smith's description of his case of chronic monocytic leukaemia in the *Journal* of July 3 (p. 1), which, as he pointed out, is of special interest on account of the extreme splenomegaly and absence of anaemia. His statement, however, that a palpable spleen is unusual in this type of leukaemia appears now to require modification in the light of Edwin E. Osgood's recent analysis of 133 cases of monocytic leukaemia, published since Dr. Smith's article went to press (*Arch. int. Med.*, June, 1937). Osgood shows that, while not a constant finding, a palpable enlargement of the spleen is quite a common feature. I doubt if it is wise to gauge the chronicity of a case by the size of the spleen. In the case recorded by me last year (*Liver-*

pool med. Chir. J., 1936, 44, 47) the clinical history was of at least eight months' duration, while the spleen weighed only 17 oz.—I am, etc.,

Liverpool, 1, July 13. JOHN DUNCAN HAY.

Prominal in Treatment of Epilepsy



SIR,—Having recently substituted prominal for luminal in the treatment of patients suffering from insanity with epilepsy, I should like to agree with the results published in the issue of July 10 (p. 61) by Dr. Guy Millman in his interesting report.

It has been, I believe, a common experience to find that luminal controls the fits only at the cost of aggravating the aggressive irritability typical of the demented epileptic. With prominal, however, the decrease in the number and severity of the fits is not followed by an exacerbation of the non-convulsive outbursts of ill temper, and the period of confusion which often follows the fit appears to be appreciably shortened. All these factors are of considerable importance in the institutional care of the epileptic patient.—I am, etc.,

Southall, Middlesex, July 14. L. MCL. CURTISS.

Hereditary Sebaceous Cysts

SIR,—Last week a woman asked me to remove several sebaceous cysts from her scalp. Remembering the interesting article on hereditary sebaceous cysts in the *Journal* of May 8, I inquired if other members of her family were affected, and from her information compiled the following tree.

I removed seven cysts varying in size from a grape pip to a damson; the eighth was as yet too small to remove. The contents of two were rather greyer in colour than usual. I have not been able to examine the other affected members of the family so do not know if the numbers given are accurate or only the number of cysts large enough to attract attention.—I am, etc.,

Lee-on-Solent, July 11. EMILY A. C. WILSON.

Ocular Headache

SIR,—I read with much interest the article on ocular headache by Mr. D. Stenhouse Stewart (*Journal*, July 10, p. 59). In this he outlined a plan by means of which the general practitioner may more easily diagnose or exclude an ocular cause for headache. Any help which can be given in this direction will certainly be appreciated, and though I naturally agree with much that the writer has said I find myself at variance on one or two points. I must first qualify my criticisms by saying that Mr. Stenhouse Stewart did not maintain that by following his routine every headache of ocular origin could be diagnosed and the patient sent for further examination. His paper inferred, however, that the majority of such patients could be singled out. The investigation outlined by the writer consisted of the use of Snellen's test type, the ophthalmoscope, and some simple piece of apparatus for estimating binocular muscle balance at reading distance; with each of these I will deal in turn.

When a patient is unable to read 6/6 with one or other eye, then, excluding retinal disease, that eye is either short-sighted, very long-sighted, or has a considerable degree of astigmatism. The myope will rarely complain of headache; the hypermetrope may occasionally do so if he does much close work, and the patient with the high astigmatic error is more likely to complain of defective vision than of headache. A large percentage of patients with headache will read 6/6 or 6/9 with each eye separately. Everyone agrees that the ophthalmoscope should be used more extensively than it is, as much valuable information can often be got from the fundal picture, but, in my opinion, it is of no use in helping one to decide whether a headache is due to eye strain. On very rare occasions a practitioner may be able to see a choked disk, and so confirm a diagnosis of intracranial neoplasm, but for the one headache so produced there are many hundreds due to eye strain.

With regard to the use of the convergiometer, the great majority of ophthalmic patients have an exophoria—a tendency for the eyes to diverge—at reading distance, and if this is so, according to the writer, "all is reasonably well" and eye strain may presumably be excluded as a causal factor. Then, again, I have never found a low degree of esophoria—a tendency to convergence—cause discomfort for close work. Because many hypermetropes have to accommodate their eyes excessively to read they have an esophoria at this distance, but on correcting their hypermetropia by suitable plus lenses the muscle balance is restored. The headache, surely, is due to the excessive contraction of the ciliary muscle, and not to the demand put on the external recti to correct the convergence, as suggested in the article. Imbalance of the ocular muscles, though it may cause headache in some, is more responsible, I think, for a feeling of discomfort and strain than it is for actual headache. For example, old patients with a high degree of exophoria will complain of an inability to read for more than a few minutes at a time, even though their spherical correction is sufficiently strong. Others, again, will experience relief by keeping one eye closed.

I cannot agree with Mr. Stenhouse Stewart when, referring to the correction of small astigmatic errors, he says that "the relief of headache by correction of such errors is often due to the restoration of normal muscle balance by adequate glasses." It is easy to understand that by fully correcting hypermetropia one can reduce a tendency to converge, and similarly with myopia a tendency to diverge, but it is difficult to see how a small astigmatic correction will have any appreciable effect on a state of ocular imbalance. When a small astigmatic error is corrected in a patient suffering from ocular headache he is immediately relieved of his discomfort, and there seems to be no reason to doubt that this refractive error has given rise to the headache by causing some kind of strain on the ciliary muscle. In my experience the great majority of ocular headaches are due to low degrees of hypermetropic astigmatism alone or combined with some simple hypermetropia, often occurring in patients whose vision is 6/6 and whose lateral muscle balance, though not perfect, is within normal limits. In the case of young children, although I have examined a very large number of them for all manner of refractive errors, I have been amazed to find how very seldom one meets with a complaint of headache. This, however, only applies to young people under the age of 12 or 13, after which time ocular headache becomes increasingly common.

I would say that a careful history taken from the patient is a better guide to the practitioner in helping him to make at least a tentative diagnosis of ocular headache than any test he may apply, short of retinoscopy. It is true that the type and situation of the headache, varying as they do so tremendously, are not of very much assistance, but the time factor gives a better clue. Thus a headache coming on in the late afternoon in a patient working in an office, especially under artificial light, is invariably ocular. Others who have reached the age of 40 or more may complain of headache after prolonged reading or sewing, due to the onset of presbyopia. Quite commonly older people who already have glasses for close work will complain of headache in the early morning following an evening spent in reading, and here an increase in the strength of the lenses will cause a disappearance of the symptoms. By far the best test for headache due to eye strain is to ask the patient if a headache comes on after near work, or at the theatre, or, better still, the cinema, or whether it develops after such an entertainment. Now that cinemas are so much better ventilated than they were several years ago it is fairly safe to assume that a headache brought on by a visit to one of them is ocular in origin.—I am, etc.,

London, W.1, July 12. L. G. SCOULAR.

Histamine in Anaphylaxis

SIR,—I think the presence of histamine with eosinophil cells in the secretion of the respiratory tract, as mentioned by Dr. James Adam in the issue of July 10 (p. 88), is a constant phenomenon in all so-called allergic reactions. Applied as a scratch test, the typical plus five reaction results and eosinophil cells are found on section. Injected into animals histamine produces all the symptoms of anaphylaxis, varying exactly as do the symptoms of that syndrome in the different species injected. If the lungs of a sensitized guinea-pig or a strip of uterus is perfused with the protein to which they are sensitized histamine appears in the perfusate. Histamine is not found in the anaphylactoid reactions after the injection of barium, etc. That portion of the pituitary gland containing histamine and used therapeutically to contract the uterus stains with the eosin dyes.

It would thus seem as if anaphylaxis were due intermediately to the formation of histamine, and that when histamine is present eosinophil cells appear, possibly as carriers of histamine in sealed containers to the liver and other parts for destruction or excretion.—I am, etc.,

London, W.1, July 13. FRANK COKE, F.R.C.S.

Carcinoma of Rectum in a Girl of Twenty

SIR,—Mr. W. G. Evans is to be congratulated on his treatment of carcinoma of the rectum by means of radium (*Journal*, July 10, p. 64). There is only one point that I am not clear about, and that is whether or no a preliminary laparotomy was done in order to determine the presence or absence of lymphatic or liver involvement; presumably there was none, as the patient survived after four years. In my case there was a gland the size of a walnut in the mesosigmoid which showed carcinomatous deposits, and to my mind the treatment of colostomy followed by abdomino-perineal resection was the only method permissible.—I am, etc.,

R. RUTHERFORD, F.R.C.S.

Longtown, Cumberland, July 14.

Precipitate Labour

SIR,—The following unusual case of pregnancy with precipitate labour may merit inclusion in your columns.

At about 7 p.m. on June 26 I was called out to see a patient. The messenger could give no information as to what was wrong, and although I arrived at the house within five minutes, at least fifteen minutes must have elapsed between the time I was sent for and my reaching the house, where I found that the patient had recently delivered herself of a full-term male infant, her first child.

The curious part of the case is the history. The patient, aged 24, was married, and had always been regular with her periods, which came on approximately every three weeks and lasted three days. The amount of loss was scanty, and this was no doubt due to her anaemic condition. Throughout the whole of the pregnancy she had seen her periods regularly, and although she admitted that she had noticed her abdomen becoming larger, she had merely thought she was putting on weight. She also said she had felt something move inside her abdomen from time to time, but she put this down to flatulence.

On the day the baby was born she went to work at the factory as usual, but asked permission to go home early as she "did not feel very well." When she arrived home she found that there was slight bleeding from the vagina, and as her ordinary period was then due she took no further notice of this. In fact, she did some heavy housework and then cooked the dinner. After this she laid on the bed, as she felt tired, not troubling to undress. She thinks that she must have been "half asleep," when she felt something between her legs, and heard the infant cry. She was so surprised as well as terrified that she "pulled the infant to her bosom," and in doing so she must have severed the umbilical cord. It was only then that she realized what had happened and sent for me.

When I arrived there was no haemorrhage from either end of the umbilical cord, which was completely severed some six inches from the infant's end, and the umbilical vessels were collapsed. The placenta had already separated, and only needed expression from the vagina. The perineum was intact. Beyond ligaturing the umbilical stump there was very little left for me to do. The puerperium was uneventful.

The outstanding features of this case are: (*a*) the regularity of the periods during the entire pregnancy, (*b*) the absence of vomiting during the early stages of pregnancy, (*c*) the painless labour, (*d*) the unruptured perineum in a primipara without medical aid, the baby weighing 9 lb., and (*e*) the absence of any ill effects to either mother or infant resulting from the severing of the umbilical cord. Any one of these features is in itself unusual in average maternity cases, so that a combination of them all must indeed be a rare "event."—I am, etc.,

J. HAROLD RIPLEY, M.R.C.S., L.R.C.P.

Tottenham, N.17, July 6.

Noise Outside Hospitals

SIR,—I have just been discharged from a nursing home after an operation which caused me neither pain nor serious discomfort. I mention this fact as I do not want it to be thought that I am complaining on my own account; but I wish, so far as possible, to obtain backing from the medical profession on a complaint, in many cases a serious one, which patients in these homes have, I believe, very good grounds for making, and the reason for which, even to one as little ill as I was, was most noticeable. This is the absolute lack of any decency or consideration on the part of a great many of the motoring public.

During the day I can understand that it is difficult to do much to prevent a great deal of the noise, but surely

at night some sort of consideration towards the large number of invalids might be shown. Hooters were blown incessantly—all sorts of strange hooters, making all sorts of weird noises. The question of silencers was entirely disregarded. Speeding up the engines while going through the low gears and starting, after signal lights had held up the vehicle, was carried to the *n*th degree. I had the feeling that there were a great many young people dashing about, no doubt on their lawful occasions, in very antiquated cars, who wished to draw attention to what fine fellows they were (and what ancient vehicles they were driving!) by making a quite unnecessary noise.

I feel certain that if sufficient medical backing were given to the gravity of this nuisance there would be practically no opposition in the House of Commons to the passing of measures which would inflict such penalties that this sort of thing woud be stopped. But it would be of very little use taking this question up unless one were assured of the support of the medical profession. Unfortunately in the House we have very few doctors who could speak on the subject, but, as I have said, I am certain that all Members would lend a sympathetic ear to any suggestion to put an end to the state of things which exists, and would assist in the rapid passing of any Bill which had the prevention of this nuisance as its object.—I am, etc.,

N. STEWART SANDEMAN.

House of Commons, July 12.

Universities and Colleges

UNIVERSITY OF OXFORD

In congregation on July 17 the following medical degrees were conferred:

D.M.—J. A. Boycott, Ella J. Cockram.

B.M.—J. Mason, M. A. Partridge, C. B. I. Willey, I. F. Rose, B. M. Thornton, R. B. Niven, A. F. Smith, J. L. Reid, W. Wynne Willson, A. L. Young, J. B. M. Green, Alice J. M. T. Barnes, Jean M. Sherring, Rebecca Billig.

UNIVERSITY OF CAMBRIDGE

The E. G. Fearnsides Scholarship, of the value of £100, offered in alternate years for the encouragement of clinical research in organic diseases of the nervous system, has been awarded to A. M. Barry, M.A., M.B., B.Chir., of Pembroke College.

UNIVERSITY OF LONDON

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY

The following candidates have been approved:

Eleanor K. Abbot, I. A. Abou Sinna, P. Arunachalam, C. S. Chatterjea, Phyllis M. Fraser, M. I. Ghattas, H. H. Navid, D. W. Smithers, R. C. W. Staley.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH.—J. K. Adranvala, Beatrix H. Bakewell, Lalage R. A. Benham, D. M. Blair, Kathleen G. Brimelow, P. N. Chatterjee, *A. B. Christie, Kitty K. Conrad, J. S. Cookson, Teresa I. M. Craig, Iris M. Cullum, C. F. Cumings, Enid S. Davies, B. K. de Silva, S. Graham, Eva M. Gray, E. H. Harte, R. M. M. Hunter, J. D. Lendrum, S. E. D. Masilamani, B. B. Mukerjee, D. Murray, A. F. S. Perera, Violet M. Spiller, Margaret B. Steel, Tsung-Sing Sze, *J. W. P. Thompson, A. F. Turner, V. M. Vatve, Sarah C. B. Walker, L. A. F. Wiles, Isabel A. M. Woods.

* Awarded a mark of distinction.

UNIVERSITY OF MANCHESTER

The following appointments have been made: Dr. E. L. Patterson as assistant lecturer in anatomy; Dr. Margaret I. Williams as assistant lecturer in applied physiology; Drs. D. D. Cranna, D. A. Richmond, and F. W. Smith as demonstrators in anatomy; Dr. John Yule as clinical lecturer in infectious diseases; Dr. Harold Simms as honorary dental surgeon; Drs. J. C. Bramwell, Stanley Hodgson, and Mr. E. E. Hughes as members of the Board of the Faculty of Medicine.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M.D.—A. J. O'Connor, J. B. Patrick, H. T. Ryan, W. C. Sloan.

FINAL MEDICAL EXAMINATION.—*Part I, Materia Medica and Therapeutics, Pathology and Bacteriolgy:* *M. O'C. Drury, *F. L. Willington, †Sylvia M. Hall, †C. B. Robinson, †M. E. Tapissier, †F. de B. Magee, Annie W. Megaw, R. J. Mitchell, F. J. Murray, J. A. O'Connell, J. W. B. Paton, Eileen E. Perry, M. I. Robinson, T. L. Ross, Kathleen E. Shannon, J. S. S. Thompson, J. B. Upton, D. G. C. Whyte, E. L. Wilson, G. N. Wilson, K. S. Wilson, W. R. Wright.

* With commendation. † Second-class honours.

C. Uggeri (*Arch. ital. Chir.*, 1937, **49**, 4, p. 361) states that while he found it impossible to produce aneurysms either in animals or man as the result of a single trauma, he succeeded in producing an aneurysmal sac with fibrinous walls in dogs after repeated attempts. According to him, sacs of this kind are not due to distension of the vessel by a thrombus occluding the arterial wound, but are the result of thrombotic deposits within the cysts.

Obituary

SIR THOMAS MYLES, C.B., M.D., F.R.C.S.I.

Consulting Surgeon, Richmond Hospital, Dublin

We regret to announce the death at his home in Leeson Park, Dublin, on July 14, of the distinguished surgeon Sir Thomas Myles, a former President of the Royal College of Surgeons in Ireland.

Thomas Myles, son of John Myles of Limerick, was born on April 20, 1857, and studied medicine at Trinity College, Dublin, graduating M.B., B.Ch. in 1881, afterwards proceeding to the M.D. degree with distinction. In 1885, on becoming F.R.C.S.I., he was appointed secretary of the Dublin Hospitals Commission, having previously served as house-surgeon at Steeven's Hospital.

In 1889 he was appointed professor of pathology at the Royal College of Surgeons, afterwards acting as examiner in surgery and occupying the presidential chair in 1900–2. He was for many years visiting surgeon to Jervis Street Hospital and to the Richmond Hospital. He received the honour of knighthood in 1902 and represented his College on the General Medical Council from 1905 to 1911 and again from 1933 until the time of his death.

Sir Thomas Myles was an honorary surgeon to the King in Ireland throughout the reign of his late Majesty, and medical referee for the Treasury in Ireland. On the outbreak of war he was appointed consulting surgeon to the Irish Command with the temporary rank of lieut.-colonel, R.A.M.C. He was promoted colonel, A.M.S., and created C.B. in 1917.

Sir William I. de C. Wheeler sends the following appreciation:

The death of Sir Thomas Myles leaves a blank not only in the ranks of the medical profession in Dublin but amongst a large community of friends and old pupils at home and abroad. Apart from professional ability of a high order, his intellectual and physical vigour aroused the interest and admiration of all who knew him. "Tom" Myles was a striking personality; it is difficult to picture his surroundings in his absence. He was a staunch and loyal friend. He was gifted with a vivid memory, his knowledge of literature was deep from endless reading, and as a speaker he was impressive and amusing. In discussions and debate he baffled opposition; in the end his views usually prevailed.

I knew him intimately for over forty years. First as a child, then when I was a medical student, and afterwards in close friendship in the many activities of surgical life. The help and encouragement he gave to juniors were whole-hearted and unstinted. A few weeks ago I had a letter recalling memories and mingling the old robustness with characteristic humour. As a young man he devoted a considerable amount of time to the study and teaching of anatomy. His memory was such that to the end of his active years he was able to recite the anatomical relationships in almost any region of the body. In addition, while still young, he became professor of pathology in the Royal College of Surgeons Medical School. With this strong foundation, reinforced by his personal magnetism, he built up an extensive surgical practice and became recognized as one of the most successful teachers of his day. His lectures at the Richmond Hospital attracted large classes. The students remained his disciples in after-years. He became President of the Royal College of Surgeons and was its representative on the General Medical Council at the time of his death. During the war he served the Army Medical Administration with ceaseless energy; his close friends were Lord Moynihan, Sir Robert Jones, and the Director-General, Sir Alfred Keogh.

In conversation "Tom" Myles made a point of avoiding professional topics. He delighted his friends with apt quotations from Shakespeare or from the many modern writers with whom he was so familiar. His company was sought on all sides, his companionship was instructive and entertaining. In the realm of sport he was equally conspicuous. He told of his adventures as an amateur heavyweight boxer. In later years he became an enthusiastic yachtsman; he seldom missed a Rugby football match of major importance. His surgical writings and operative work now belong to a past generation: they are still worthy of study. Notwithstanding all these qualities his intimate friends will remember him best by the charity and sympathy which followed him to the bedside of his hospital patients. He had retired from active surgical practice, but although handicapped by some deafness he retained that commanding and unconventional personality which made him an outstanding figure in whatever circle he moved.

He raised to a higher level everything he touched. Mediocrity and commonplace in his hands reached efficiency and respect. He set a great example. No one in our time can hope to replace him.

Sir Robert H. Woods writes from Dublin:

By the death of Thomas Myles Ireland has lost one of her most remarkable men. Though he won his fame as a surgeon surgery was only one of his many activities. He was interested in all things human. His retentive memory, fed by omnivorous reading, rendered him a veritable storehouse of information which he was at all times ready to impart; and there were few subjects of discussion on which he could not deliver a mature and enlightening opinion. In Baconian phrase he was full, ready, and exact. He had an intrepid mind that broke through the entanglements of catchwords and phrases, and arrived at what appeared to him to be the truth with wonderful ease. The vigour of his expositions sometimes vexed less independent minds, but he was never gratuitously offensive, and his points were made with as much modesty as the importance of the subject seemed to allow. Mentally as well as physically he was a big man, and no one could talk to him without knowing it. With the strength of a giant he was never tyrannous. Like a good boxer, he could hit hard and straight, but he was utterly devoid of petty jealousy, and was never known to bear malice. He never forgot a friendly act nor desired to remember an unfriendly one. He had a complete and good-humoured tolerance for those whose views differed from his, and in an intimacy of over fifty years I never knew him to be out of temper. Shakespeare was his favourite author, and few men of his time could compete with him in his textual and critical knowledge of the plays.

His knowledge of modern history was vast, and he could talk equally well on classical and current literature.

He scored his first success as a "grinder," and no one who was privileged to be a member of his class could easily forget the clearness of his explanation of a difficult subject. A born teacher, his enthusiasm made hard work attractive. But hard work under his tuition never connoted drudgery. Like the Great Playwright, he understood the value of comic relief in the middle of strain too well to repress an occasional flippancy during his grinds; and indeed he more often himself led the laughter by some ludicrous comparison or quaint turn of phrase that helped to fix the lesson more effectively. So much was this the case that none of us missed a grind if we could possibly attend, for we knew that the fun would more than compensate for the toil.

I was his colleague for fifteen harmonious years from 1891. At that time asepsis was beginning to displace antisepsis in theatre work, and Myles was one of the pioneers of the newer method. He was the first surgeon that I saw using gloves; they were of cotton, for rubber had not yet come into use. His first sterilizer was a fish-kettle on the kitchen fire of the old Richmond Hospital, to the amazement of the cook, who supposed that he "wanted to soften the instruments." I think it was he, though it may have been his fidus Achates, Richard Lane Joynt, who at this time perpetrated the delightful parody of Polonius: "And boiling dulls the edge of cutlery." Even to the end the boy was never lost in the man, and an after-dinner speech from him was a delight. Up to a short time before his death he seemed to have discovered the secret of perpetual youth, for his intellect was as clear and his bodily strength as vigorous as that of most men of half his age. We shall not look upon his like again.

Mr. A. B. Mitchell writes from Belfast:

A very great Irishman has gone to his long rest. Sir Thomas Myles was an outstanding personality in any company. His conversation was always fascinating because of the extraordinary range and accuracy of his knowledge and the simplicity and forcefulness with which he expressed himself. His acquaintance with history was profound. He was one of our greatest Shakespearian scholars, and constantly quoted his favourite author with a fervour and suitability that was most impressive. He was endowed with a colossal memory. He was a voracious reader. A book once read was mastered; he could refer to its individual characters years afterwards as if he had lived and moved amongst them. His wonderful capacity as a teacher of medicine and surgery will never be forgotten till his last pupil has gone to join him in the "Everlasting Land." It is not too much to say that one's first visit to "Tom Myles's Grind" was a revelation. The lucidity, brevity, accuracy, and virility of his descriptions of disease were altogether unique. He prepared more than 1,000 young men for various medical degrees, and for entrance examinations for the Army, Navy, and Indian Medical Services. His pupils have attained the foremost positions in every part of the British Empire. Wherever they went they carried with them not only profound admiration but a deep affection for their great teacher. It is impossible to overestimate his influence upon the lives and character of those who came under his magnetic personality. Others will deal with his skill as a surgeon; I have confined myself to some personal characteristics of my beloved teacher and lifelong friend.

WILLIAM LANG, F.R.C.S.

Consulting Ophthalmic Surgeon, Middlesex Hospital; Consulting Surgeon, Royal London Ophthalmic Hospital

We regret to announce that Mr. William Lang, the veteran ophthalmic surgeon, died on July 13 at the age of 84. He retired from practice some ten years ago, but continued to live in Cavendish Square.

Born at Exeter on December 28, 1852, the youngest son of Isaac Lang, he was educated privately and at the London Hospital, where he held the posts of house-physician, house-surgeon, demonstrator of physiology, and demonstrator of anatomy, after qualifying as M.R.C.S. in 1874. While at the London he came into close touch with James Edward Adams, the ophthalmic surgeon, and this was the beginning of a long and fruitful career in the diagnosis and treatment of eye disease. Lang became a Fellow of the Royal College of Surgeons in 1879, and five years later, when Adams resigned from the staff of the Royal London Ophthalmic Hospital (Moorfields), he was elected to the vacancy. About the same time he was also appointed ophthalmic surgeon to the Middlesex Hospital, and at these two institutions he exerted a powerful though quiet influence on young eye surgeons. On his resignation from Moorfields in 1912 he was appointed consulting surgeon. Those who had the advantage of being trained by William Lang will recall to memory his *Methodical Examination of the Eye*, a book which was "the ophthalmological Bible of their junior days." It came out in 1895 and was labelled Part I; all who worked in his clinic at Moorfields or the Middlesex looked forward to the publication of the remaining part or parts—but none ever appeared. He was also a pioneer in the conception of focal sepsis. Many years ago he taught that iritis commonly had its origin in some focus of inflammation elsewhere in the body.

William Lang had a cultivated taste in books and pictures, but was reticent and retiring. In the days when he lived at Chiswick he enjoyed the friendship of William Morris and his group, and bought the volumes from the Kelmscott Press as they came out. He was twice married and had a son and a daughter. The son, Basil Thorn Lang, F.R.C.S., died early in 1928 at the age of 47. He was an ophthalmologist of exceptional ability and a man of great originality of mind and mechanical inventiveness.

We are indebted to Sir Arnold Lawson for the following appreciation:

I doubt if there is anybody who can claim so intimate and so long an acquaintance with William Lang as myself. I first came into contact with Lang as one of his out-patient dressers at Middlesex Hospital. Later on I was his house-surgeon at the same hospital, and subsequently, until my election to the staff at Moorfields, I was his chief clinical assistant at Middlesex. Then I became his colleague on the staff of Middlesex as well as at Moorfields, and all this means that I was in close touch with his work for a great number of years. I am glad to

write some notes about Lang. He was my first teacher in ophthalmology, and I owe a great deal to him. There are many who, like me, could say much about his work, but nobody who could say it with a greater reverence or a greater appreciation of his very high qualities.

Although Lang was essentially a "Middlesex man" he received his early training at the London Hospital, where he entered as a student in 1870. There he served as house-surgeon and house-physician, and for a time was a demonstrator in anatomy and physiology. In 1879 he took his Fellowship at the Royal College of Surgeons, and in 1881 he was elected ophthalmic surgeon and lecturer on ophthalmology to the Middlesex Hospital. This post he filled with great distinction until 1914—a period of thirty-three years—when, owing to the age limit of 65, he retired from the active staff and was elected consulting surgeon to the hospital. In 1884 Lang was elected assistant surgeon to the Royal London Ophthalmic (Moorfields) Hospital, and in due course became full surgeon, serving in that capacity until 1912, when he was elected to the consulting staff of the hospital. At Moorfields the age limit is somewhat younger than at Middlesex, and it was on this account that he retired from active work at Moorfields rather earlier than he did at Middlesex.

Lang was one of the original 113 members of the Ophthalmological Society of the United Kingdom, a band of pioneers in modern ophthalmology who formed themselves into a society in 1880 under the presidency of Sir William Bowman. Many distinguished names, since writ large in the annals of ophthalmology, are to be found in the list of original members, and that of William Lang will be numbered among them. Lang was one of the last two survivors, and his death leaves only Sir Lindo Ferguson to represent the founders of the society. Lang always took a keen interest in the work of the society and wrote many articles in the annual *Transactions*, retaining his membership to the last. He was a vice-president of the society, and in 1903 acted as president during the interregnum caused by the death of Dr. David Little, who was president at that time. Lang was a prominent member of the Ophthalmological Section of the Royal Society of Medicine, and was one of its early presidents, contributing much to the discussions and evincing great interest in the welfare of the Section.

Lang was essentially a great clinician. He wrote many papers recording his experiences in a diversity of subjects appertaining to the eye, and in this respect will probably be best remembered by his early recognition of the importance of focal sepsis in the aetiology of chronic inflammatory conditions of the eye. He was always an advocate for massive doses of vaccines, and was accustomed to commence proceedings with a dose which would startle a good many bacteriologists nowadays. Undeniably, however, he met with a large measure of success in many cases which had resisted all the usual remedies. His contributions to the technique of ophthalmic surgery were considerable. Although he laboured under difficulties engendered by a marked tremor of the hands he was a beautiful operator, and the tremors always ceased when he was about to do something which required particular accuracy and delicacy of touch. In point of fact these tremors had nothing to do with what are commonly known as "nerves." I remember very well at the time of the great International Medical Congress in London before the war there was to be a large gathering of European ophthalmological professors to see our work at Moorfields. All we younger surgeons were rather shy of exhibiting our prowess under the close scrutiny of learned foreigners—for of course in the operating theatre at Moorfields all onlookers are very close indeed to the operating surgeon. Lang, however, was delighted to be showman, and gave a most masterly exhibition of beautiful handiwork, which was the more remarkable because of the doubts which were uppermost in one's mind before he really started. Lang had a mechanical mind, too. His eye speculum, which guarded the lashes and kept them out of the field of operation, found instant favour, and is in general use now. Also he introduced twin knives for the division of anterior synechiae which have not been surpassed. He was interested in the treatment of lachrymal troubles, and his lachrymal syringe and blunt dissector and scoop are well known. But perhaps his best-known contribution to the mechanical side of surgery was his advocacy of inserting an artificial globe into Tenon's capsule after enucleation as a means of preventing the deformity following on the shrinkage of the orbital tissues and so permitting good movement of the artificial eye. Lang was led to introduce this operation because of the fear of sympathetic uveitis that haunted Mules's operation of evisceration of the contents of the globe and placing a prothesis on the ocular stump. This operation was, however, received with mixed favour. I believe it to be perfectly free from danger of sympathetic inflammation in the other eye myself, but others were not so favourable, and there proved to be considerable difficulty in keeping the artificial globe in a central position. After a time there was apt to occur a certain displacement, which negatived to some extent the usefulness of the operation, and sometimes made necessary the removal of the globe.

Lang was a splendid teacher. He was fond of the students—dear boys, as he habitually called them when trying to instil the elements into the usual mixed crowd of out-patient men. He had an arresting and genial personality which insisted on and commanded attention from even the dullest of them. One *had* to learn when Lang wished it, for otherwise there was a gentle sarcasm handed on to the unhappy man which caused general amusement to the onlookers and made the recipient very conscious of his futility. He was a very hard and conscientious worker himself and expected the same from his assistants, being very appreciative, however, of work well done. He was a very keen observer, and this, with his attention to detail, brought him great success in his private practice. I can certainly say that few people who consulted William Lang ever transferred their cases to another specialist. He would enter on a dull case of refraction with the same complete attention to detail as he would give to more interesting work, with the result that he inspired great confidence in all his patients in both his hospital and his private practice.

Socially he was not athletic, but he was fond of golf and took great interest in golf matches between the staff and the students at Middlesex, presenting a most beautiful bronze statuette of an athlete as a trophy for an annual competition. His golf was not of a high order, but he thoroughly enjoyed it, and a match with him when the opponent, like myself, was indifferently bad was always a keen and amusing affair. Lang hated public speaking, and especially avoided after-dinner speeches whenever he could. When we gave him a great dinner on his retirement from the active staff of Middlesex he had of course to make a speech of thanks, the thought of which disturbed him so much that we had quite a difficulty in getting his consent to the dinner.

Lang's later life was clouded with much sorrow. He married twice, and his second wife predeceased him by

many years. By his first wife he had a son and daughter. His only son, Basil, was brilliantly clever, and, following in his father's footsteps, was eventually elected to the staff at Moorfields only to die a few short years later from pneumonia at a time when his prospects were of the brightest. Lang felt his son's death very keenly, and soon afterwards began to exhibit symptoms of the long pathetic illness which eventually brought his life to a close. For several years he was comforted by the complete and marvellous devotion of his daughter, who literally gave her life to helping him and to soothing his failing powers.

Dr. AUGUSTUS ROLLO BALMAIN, deputy M.O.H. for Ilford, died from a sudden heart attack while motoring in the Rhineland with his wife; the funeral took place at the village church of Hockering, outside Norwich. Dr. Balmain graduated M.B., B.S.Lond. in 1916, and took the D.P.H. of Oxford in 1920. After studying at Birmingham and the Middlesex Hospital he held house appointments at the Birmingham General Hospital, and was formerly assistant M.O.H. for Colchester and Birkenhead, and county oculist and assistant school medical officer for Somerset. During the war he served with the 14th C.C.S. in the East African Expeditionary Force. He obtained the M.D. in 1929. Dr. A. H. G. Burton, M.O.H. for Ilford, writes: Dr. Balmain was a modest, unassuming, retiring man, and probably only his immediate chief understood his worth. He came to Ilford in 1927 with the highest recommendations from his previous medical officers. He had a fine knowledge of modern medical work, and was himself a doctor whose opinion could be implicitly relied upon on any medical matter. He had charge for some years of the diphtheria immunization clinics and of the open-air school, and was inspector of nursing homes and of massage establishments in Ilford. In addition he collaborated with me in a good deal of research work and case recording which would have been impossible for me to carry out without his assistance. We published together seven articles, which appeared in the *Lancet* between 1928 and 1931. At the time of his death we were considering the possibility of the scientific estimation of the value of the open-air school, and the reason why it benefits some children and not others. Some preliminary work had already been done, but it will have to be left for another hand to complete it. Dr. Balmain was a loyal colleague, ever anxious to assist any members of the staff whom he was able to help. He carried himself gallantly through the great war, serving in the East African Expeditionary Force throughout in spite of many attacks of malaria, and remained as captain in the R.A.M.C. Special Reserve.

Dr. DANIEL BARTHOLOMEW FOLEY, who was for many years in practice at Wombwell, Yorkshire, died recently at Southport, aged 72. He studied medicine at Queen's College, Cork, obtaining the L.R.C.P. and S.Ed. and L.R.F.P.S.Glasg. diplomas in 1889, and soon afterwards entered into partnership with his brother, the late Dr. James Foley. After some forty years as pit doctor at Darfield Main Colliery, during which he was prominent in ambulance work, Dr. Daniel Foley retired to Southport in 1931, and the Wombwell Urban District Council gave his name to one of the thoroughfares on its new housing estate in recognition of his public services to the district. He had been a member of the British Medical Association for thirty years.

Dr. ROBERT HARGREAVES, a Sheffield medical practitioner, collapsed while driving his car in one of the busiest central thoroughfares of the city on July 12, and died a few minutes later, before admission to the Sheffield Royal Hospital. Dr. Hargreaves was born in 1891, and studied medicine at Cambridge and University College Hospital, graduating B.A. in the Natural Sciences Tripos and afterwards obtaining the M.R.C.S. and L.R.C.P. diplomas. During the war he was medical officer to the 9th Battalion Royal Fusiliers with the rank of Captain R.A.M.C.(T.), and at the end of 1918 he took over his father's practice. He was a member of the Sheffield Medico-Chirurgical Society and joined the British Medical Association twenty years ago.

Dr. HENRY WILSON died at Cheadle, Cheshire, after a long illness, on June 25 in his seventy-ninth year. A student of Owens College, Manchester, he obtained the M.R.C.S. diploma in 1881, and after serving as house-surgeon at the Manchester Royal Infirmary, and senior resident medical officer at St. Mary's Hospital, Manchester, he settled in practice at Cheadle. Dr. Wilson was a justice of the peace for the county of Chester, a past-president of the Stockport Medical Society, and a member of the Manchester Pathological and Medical Societies. He joined the British Medical Association as long ago as 1884.

Medical Notes in Parliament

On July 13 the Local Government Superannuation (Scotland) Bill was before the House of Commons. On a motion for third reading Rear-Admiral Beamish drew attention to Clause 12 which, he said, discriminated against voluntary service counting for service with a local authority. The people who voluntarily served in the Forces of the Crown in the war and, again voluntarily, extended their service after the armistice, were, under the Bill, excluded from counting for pension their period of military service. Dr. Elliot said that it was the intention of the Government to recommend the insertion of an amendment in the House of Lords to extend the period during which service with the Forces should count from November 11, as now in the Bill, to December 31, 1920. The Bill was read the third time.

In the House of Lords on July 19 the Local Government Superannuation Bill passed through committee, and the Local Government Superannuation (Scotland) Bill was read a second time. The Finance Bill was read a first time.

In the House of Lords on July 19 the Summary Procedure (Domestic Proceedings) Bill and the Cinematograph Films (Animals) Bill were read the third time and passed.

In the House of Lords on July 19 the Royal Samaritan Hospital for Women Glasgow Order Confirmation Bill passed through the report stage.

In the House of Lords on July 20 the Royal Samaritan Hospital for Women Glasgow Order Confirmation Bill was read the third time and passed. Later that day the Bill was received in the House of Commons.

The House of Lords this week discussed the report of the Royal Commission on Palestine. The report stage of the Factories Bill was set down for July 22. In the House of Commons there were debates on Palestine, foreign affairs, the Milk Amendment Bill, and the Estimates for the Department of Health, Scotland.

On July 20 the Royal Assent was given to the Livestock Industry Act.

In the House of Commons on July 20 the Milk (Amendment) Bill passed through Committee.

Supplementary Estimates published on July 20 include £85,000 additional grant to the Diseases of Animals Account in respect of tuberculosis in cattle, and of £1,500 for other diseases in cattle, making the total grants for diseases of animals services in 1937

£287,610. Contributions towards the expenses of the Milk Marketing Board in increasing the demand for milk in England and Wales are raised from £240,000 to £430,000. The similar vote in Scotland is increased from £42,500 to £60,500. These votes will be partly used in compensation in respect of milk sold at reduced prices for consumption by special classes of persons. A Supplementary Estimate of the Board of Education includes £158,000 for grants under the Physical Training and Recreation Act.

Factories Bill

The House of Lords, on July 12, went into committee on the Factories Bill. On Clause 20 (Cleaning of machinery by women and young persons) Lord BERTIE OF THAME moved to allow the cleaning of machinery by these classes of workers with the special consent of the Home Secretary. He said this might be advisable in an emergency such as war. The EARL OF MUNSTER, in resisting the amendment, said that from 1931 to 1935 accidents to women and young persons through cleaning machinery numbered 3,758. The amendment was withdrawn.

On Clause 27 (Precautions in places where dangerous fumes are liable to be present) the EARL OF LISTOWEL moved to provide that men working under dangerous conditions in confined spaces should in all cases wear a suitable breathing apparatus. The EARL OF MUNSTER said workmen found such an apparatus extremely uncomfortable and hampering to their movements. The provisions in the clause had been worked out with technical advisers and did not dispose men working in these confined spaces to any risk whatsoever. The amendment was withdrawn.

WASHING FACILITIES: NEW CLAUSE

Clause 42 (Washing facilities) was withdrawn on the motion of EARL DE LA WARR, and on the motion of the EARL OF MUNSTER the following new clause was substituted:

> "(1) There shall be provided and maintained for the use of employed persons adequate and suitable facilities for washing, which shall be conveniently accessible and shall be kept in a clean and orderly condition.
>
> (2) The Secretary of State may by regulations prescribe, either generally or as respects any class or description of factory or as respects the persons employed in any process, a standard of adequate and suitable washing facilities.
>
> (3) The Secretary of State may by regulations exempt any class or description of factory from the requirements of this section, where he is satisfied that, having regard to the special conditions under which work is carried on, compliance therewith would be unreasonable, and the superintending inspector for the division may by certificate exempt, subject to any conditions specified in the certificate, a factory from the requirements of this section where he is satisfied that, having regard to the special circumstances of the factory, compliance therewith would be unreasonable.
>
> (4) This section shall come into operation on July 1, 1939, provided that, as respects persons employed in any process in which lead, arsenic, or any other poisonous substance is used, or any process prescribed by the Secretary of State, being a process liable to cause dermatitis or any other infection of the skin, this section shall come into operation at the commencement of this Act."

Lord STRABOLGI remarked that under the new clause two years had to elapse except in especially poisonous occupations. Two years were not required for fitting up washing facilities and he hoped the matter would be looked into. The EARL OF MUNSTER said that in many factories it could not be done before that date. In reply to Lord ADDISON he promised to consider, before the report stage, whether the words "of the skin" in the last line but one of the amendment should be deleted in order to cover a case which had occurred during the war, when it was found that a considerable percentage of T.N.T. poisoning was caused not through the skin but because people from the factories put their stained hands to their mouths.

On Clause 49 (Protection of eyes in certain processes) an amendment was accepted on the motion of the EARL OF MUNSTER empowering the Home Secretary to direct the use of screens instead of goggles where this was desirable.

On Clause 54 (Basement bakehouses) Lord FARRINGDON moved a proviso that such bakehouses should in no cases be used after the expiration of five years from the date of the passing of the Act. He said it was impossible that premises used for baking underground could be hygienic. The temperatures in these places were terrific. Modern ovens were of metal and of no great weight and therefore could be moved to other positions without much difficulty. Notice of the intention to abolish underground bakehouses had been given in 1891. The EARL OF MUNSTER said nearly all the basement bakehouses which still existed were occupied by small concerns, and these small concerns were rapidly disappearing. The Government was satisfied that by the clause as it stood it was providing proper hygienic and sanitary conditions in bakehouses, and it was not prepared to end the life of the smaller classes of master bakers five years hence. The amendment was negatived. Lord FARRINGDON moved to insert a new clause prohibiting night work in bakehouses. After discussion the new clause was rejected by 34 to 9 on the ground that an inquiry set on foot by the House of Commons into night baking was not yet complete.

WORKING HOURS OF WOMEN AND JUVENILES

On Clause 70 (General conditions as to hours of employment of women and young persons) the EARL OF LISTOWEL moved to insert "it shall be unlawful for a young person under the age of 15 years to be employed in a factory." The amendment was defeated. On the same clause Lord FARRINGDON moved to substitute 40 hours for 48 hours as the maximum working week for women and young persons. The EARL OF MUNSTER said it must be remembered that it was at present legally permissible to employ persons for 60 hours a week in non-textile and 55½ hours a week in textile occupations, and the Bill laid down that legal maximum hours of employment in all factories should not exceed 48 in one week. The proposed reduction to 40 hours would result in dislocation of industry and heavy loss of production. The amendment was rejected.

Lord ADDISON moved to reduce the maximum working spell permitted without a break for women and young persons from 4½ to 4 hours. He said that during the war he had appointed a Committee on Fatigue which was succeeded by a Committee on Industrial Fatigue. These presented reports which, without exception, supported the principle that 4 hours was enough as a continuous spell of work. The amendment was negatived.

On Clause 71 (Reduction of weekly hours of work of young persons under 16) the BISHOP OF WINCHESTER moved to reduce these hours from 44 to 40. Lord ASKWITH supported the amendment. He said that the hours of work which were laid down at present for such young people were too long, and the young persons had no chance of success for keeping their bodies fit and their minds clear. After a long discussion the amendment was negatived.

On Clause 109 (Employment of women and young persons in places other than factories in processes connected with lead manufacture or involving the use of lead compounds) an amendment was inserted on the motion of the EARL OF MUNSTER applying the clause to all persons who had not attained the age of 18.

Further drafting amendments were made, the schedules were agreed to, and the committee stage was concluded.

Marriage Bill

In the House of Lords on July 15 the Marriage Bill was considered on report. Lord MOYNE moved to omit Clause 1 (No divorce within three years of marriage and provision for cases of special hardship). After debate the motion to omit was defeated, and Clause 1 was retained with the amendment made in committee of the House of Lords reducing the period of delay from five years to three years. Minor amendments were also made in the clause on the motion of Lord Maugham.

RECURRENT INSANITY

On Clause 2 (Grounds of petition for divorce) Lord DAWSON OF PENN moved an addition to Subsection (*d*). This subsection

ran: "Is incurably of unsound mind and has been continuously under care and treatment for the period of at least five years immediately preceding the presentation of the petition." Lord Dawson moved to add at the end of this paragraph: "Or whose unsoundness of mind is established to the satisfaction of the Court to be of the recurrent type, provided that no petition can be presented until five years have elapsed since the respondent was first declared to be of unsound mind." Lord Dawson said his amendment referred to what he might call "shuttlecock cases"—patients who were in and out of an asylum all the time. It was not rare to find that one spouse had been in and out of an asylum ten times in twenty years, but not necessarily for the continuous period of five years. The cyclical cases were peculiarly distressing. They went back to their homes convalescent, but by no means cured. In the early days the healthy spouse was willing to put up with that, and his amendment suggested that no petition should be presented until five years had elapsed since the first attack of insanity. But after five years, when it was clear to the Court, which would take medical evidence, that this insanity was recurrent and might go on for twenty years, the petition should be favourably considered. The majority of such cases were incurable after the time mentioned in his amendment. It was therefore cruel to compel the healthy spouse after the lapse of a number of years to receive the convalescent patient into the home every time he or she came out of an asylum, and be subject often to treatments and degradations which were particularly felt in small homes. That the patients would know they were liable to be divorced would have no influence whatever at a late stage in these recurrent cases. Asked by Lord ATKIN what he meant by "first declared to be of unsound mind," Lord DAWSON said he meant certification, and he would rather have the phrase "full certification."

Lord GORELL said Lord Dawson was clear in his own mind as to the meaning of the recurrent type, but to anyone who was not a skilled medical man "recurrent" was a vague word difficult of interpretation. Furthermore the word "declared" introduced difficulty. There was no authority to declare anybody of sound mind.

The EARL OF MANSFIELD said the Bill introduced new dangers in respect of people in institutions and voluntary patients. He was chairman of the directors of one of the Royal Asylums of Scotland with an increasing number of voluntary patients. He was afraid unscrupulous persons would try to get their periodically insane partner certified insane to avoid the financial responsibility for maintenance.

Lord MAUGHAM said the certificate of a single medical man seemed an unsatisfactory way of determining whether the person should be divorced. Those who had experience of lunatic cases knew that some doctors would certify and others would stoutly decline to do anything of the kind.

Lord DAWSON replied that if his form of words was open to objection because it did not adequately fit his intention he was prepared to withdraw his amendment and reserve the right to give a better wording on the third reading. It was right and proper that after five years the scales of mercy should incline towards the afflicted spouse. There was no great evidence that the group to which his amendment referred would in the near future be so cured that they could become normal members of society.

The amendment was negatived.

INSANITY WITHIN TWELVE MONTHS OF MARRIAGE

On Clause 7 (New grounds for nullity) Lord SALISBURY moved to insert after the reference to epilepsy in this clause the words: "Provided that if either party to the marriage shall within twelve months after the marriage become manifestly of unsound mind or mentally deficient, that fact shall be prima facie evidence that such party was of unsound mind or was mentally deficient at the time of the marriage." He said it had happened and would happen again that insanity which was not obvious at the time of the marriage became obvious immediately afterwards, and the question arose of how far that ought to be held to make the marriage null. The amendment prescribed that if insanity became apparent within a certain period of the marriage that should be prima facie evidence—not conclusive evidence—that the consent was not a good one. The period proposed was twelve months, but that was a matter of detail, and if the House thought that too long Lord Salisbury would be glad to consent to a shorter period.

Lord DAWSON said he was afraid it would not be possible to carry out the proposal in the amendment. Some of the most difficult cases of insanity were insanities of pregnancy and childbirth, and twelve months would embrace a number of cases in that group. Many such insanities were curable and were often due to temporary causes, and injustice would be caused if an amendment of this kind were passed. Lord GORELL said the promotors of the Bill thought the difficulties of the amendment too great for it to be accepted. Lord Salisbury withdrew the amendment.

VENEREAL DISEASE

On the same clause in Subsection (c), which provides for nullity if the respondent was at the time of the marriage suffering from venereal disease, Lord Dawson had an amendment to insert the word "communicable." Lord ELTISLEY said those in charge of the Bill accepted the amendment. Lord GORELL suggested that the phrase should be "venereal disease in a communicable form."

Lord DAWSON accepted this phrase and moved his amendment accordingly. He said syphilis was not communicable from one spouse to the other, or only very rarely communicable, after a year had elapsed from the time of infection. It often ceased to be communicable quite early. In practice people who had been properly treated were permitted by some authorities to marry one year afterwards, and the very most that others required was two years. After that date, although syphilis might do damage to the person originally infected, it would not do damage by communication to anyone else. This further difficulty arose that there was a blood test for this disease. Suppose, for example, that one of the parties to a marriage was infected five years before the marriage. The disease would not be communicable at the time of the marriage, yet in some instances the blood test remained positive, although at the same time on other grounds it was certain that the disease was not communicable. The paragraph as at present worded might act with great unfairness and bring in confusion. The whole question could be settled by inserting the word "communicable" or "any form which is communicable."

Lord ATKIN asked whether a man could suffer from syphilis in such a way that he might hand it to his children and yet not communicate it to his wife. Voidability of marriage ought certainly to apply to a case where a man suffered from venereal disease which he was capable of handing down to his children.

Lord DAWSON said the blood test on the wife would be part of the evidence which would show that the wife was positive. The broad answer would be that it would be so rare as not to be worth bringing into the Act for a child to be infected without the mother being infected too, certainly as concerned the blood test of each.

The House then agreed to the amendment to add "in a communicable form."

Drafting amendments were made in subsequent clauses, and the report stage was concluded.

On the motion of the EARL OF DROGHEDA the title of the Bill was altered to the Matrimonial Causes Bill, 1937.

On July 19, in the House of Lords, the Matrimonial Causes Bill was read the third time by 79 votes to 28, and passed.

Ministry of Health and Treatment of Rheumatism

Answering, on July 8, an inquiry by Mr. Edward Dunn, who asked what measures the Minister of Health proposed to combat rheumatism, Sir KINGSLEY WOOD said treatment for this varied and complex group of diseases was available in most of the voluntary general hospitals and the general hospitals owned by local authorities, and there were a number of institutions which specialized in the treatment of certain rheumatic diseases. He would continue to give careful con-

sideration to this matter, but at present did not propose to introduce any special schemes which would supersede the progressive and increasing provision now being made to combat and study the disease, provision with which his medical advisers were in close association. He could not state the number of persons chargeable to the Insurance Fund through rheumatism nor the cost and the number of working days lost through the disease. Mr. TURTON asserted that mead was an effective palliative of rheumatism.

Insured Persons Not on Doctors' Lists

On July 8 Sir KINGSLEY WOOD told Mr. Joel that the number of persons who had been insured for twelve months without selecting an insurance doctor was not available, but the number of insured persons at any given time who had not selected a doctor although entitled to do so was about 495,000 in England and Wales. A recent sample investigation of the official records kept by doctors showed that 48 per cent. of the persons who had been on doctors' lists throughout 1936 had not been seen in the year, and that the number of attendances, including home visits, per patient seen during the year was 7.1.

Agriculture Bill: Veterinary Provisions

On July 12 the Agriculture Bill was considered by the House of Commons in committee. On Clause 18 (Veterinary Inspectors) an amendment to leave out the word "inspector" and to insert "officers" was withdrawn after an explanation by Mr. Ramsbotham.

Mr. MACLAREN moved an amendment providing that the Minister should appoint a chief veterinary officer who should be responsible directly to him for the organization of the centralized veterinary service and for supervising the duties to be discharged by the veterinary officers to be appointed. The purpose of the amendment, he said, was to bring into the Ministry of Agriculture a chief veterinary inspector or officer, who should be responsible to the Minister directly and should have the same technical control over the members of the staff as the Chief Medical Officer in the Ministry of Health. After some discussion and an explanation from Mr. Ramsbotham as to the arrangements that had been made, under which the work of administration would be the responsibility of the senior administrative officer while the chief veterinary officer would continue to be responsible for the control of the professional veterinary staff and advise the Minister on all questions connected with diseases of animals, the amendment was withdrawn.

Mr. AMMON moved a new subsection providing for the transfer and attachment to the Ministry of Agriculture and Fisheries veterinary inspectors or veterinary officers wholly or mainly engaged by a local authority. Mr. RAMSBOTHAM said it was the Government's declared intention to invite all whole-time officers to accept appointment under the Ministry, and to become civil servants; it was also the Government's intention to utilize the service of the part-time officers, as far as possible, but it could not concede to those officers the status of civil servants. After further debate, Mr. W. S. MORRISON said that the position of part-time officers would be improved under the Bill. Under the new arrangements they were bound to be more extensively employed. The amendment was negatived.

Mr. W. ROBERTS moved to leave out subsection (3), and asked for some statement as to which of the many functions of the present administrative system were to be transferred and which were to be left to the local authorities and charged to them. Mr. WEDDERBURN said that the services which were going to be transferred were the duties under the Tuberculosis Order, 1925, the routine veterinary inspection under the milk and dairies legislation, the tuberculin tests under the Milk (Special Designation) Order, and the diagnostic inquiries under Schedule D. There was a long list of services which would not be transferred, such as duties relating to the administration of the Diseases of Animals Act, receiving information from owners of diseased stock, etc. The amendment was withdrawn.

Mr. JOHNSTON moved a new clause providing that Part IV of the Bill should, in so far as it applied to Scotland, be administered in consultation with the Secretary of State for Scotland, and through the appropriate departments and officers under his control. Under the Bill the Milk and Dairies Act, the Attested Herds scheme, Milk Orders, etc., would be transferred to the Ministry of Agriculture in England. After a statement from Mr. Wedderburn the clause was negatived.

The committee stage of the Bill was concluded.

Inquiry into Sickness Benefit

On July 12 Mr. HEPWORTH asked the Minister of Health whether any special inquiry was being made by his Department into the alleged existence of an exceptionally large number of applications for sick benefit, especially among women. Mr. BERNAYS said that an investigation was being made by his Department, in conjunction with the Department of Health for Scotland, into the general question of the expenditure of approved societies on disablement benefit, but no conclusions had yet been reached.

Diphtheria Immunization

Mr. W. LEACH asked, on July 15, what methods were adopted by medical officers of health to ascertain whether or not diphtheria patients had been immunized, seeing that in the majority of immunizations no certificates were issued nor did the patients bear any marks to show that they had been immunized. Sir KINGSLEY WOOD replied that it was the practice of medical officers of health to keep records of the names of all persons immunized against diphtheria under arrangements made by the local authorities. He could not accept Mr. Leach's description of this immunization as a "highly dangerous and ill-chosen experiment."

Sir KINGSLEY WOOD further told Mr. Leach that, according to the information furnished by the Cardiff local authority, out of 14,523 children who had been inoculated up to the end of 1936, 195 contracted diphtheria. During the same period 2,918 cases of diphtheria occurred among all children under 15 years of age.

House Collections for Hospitals.—Sir SAMUEL HOARE, on July 1, told Mr. R. C. Morrison that there had come to the notice of the police evidence of door-to-door collections made in the metropolitan area by persons claiming to have authority to collect old clothes, newspapers, etc., on behalf of hospitals. Inquiries made from time to time had not revealed any grounds for action on their part. Mr. MORRISON suggested inquiries to ascertain to what extent, if any, the proceeds from such collections were paid to hospitals. Sir SAMUEL HOARE said that if Mr. Morrison had information suggesting that a breach of the law was being committed in any particular instance he would look into the matter.

Imported Cheese and Disease.—Mr. LIDDALL, on July 1, asked whether the Ministry of Health obtained official certification that the herds of goats from the milk of which imported gorgonzola cheese was made were free from disease; and whether imported cheeses from foreign sources were continuously tested at our ports of entry to prevent the sale here of cheese containing germs of undulant fever or Mediterranean fever or other diseases endemic among South European herds of goats. Sir KINGSLEY said such certification and inspection were not arranged, but the matter had not escaped attention, and on the evidence available no special precautions appeared to be necessary. Any germs which might exist were destroyed during the maturing of the cheese.

Treatment at Infant Welfare Centres.—Sir KINGSLEY WOOD told Mr. Sorenson on July 1 that although separate sessions were held at many infant welfare centres for children between 2 and 5 years of age it was not usually desirable to establish separate centres. Children of all ages up to 5 were seen at infant welfare centres, which numbered 3,368 in England and Wales on December 31 last. The primary purpose of these

centres was preventive and advisory, and children when necessary were referred elsewhere for the appropriate form of treatment.

Health Conditions of Offices.—Sir KINGSLEY WOOD told Mr. Creech Jones on July 1 that he had issued a circular urging local authorities systematically to exercise their powers under the Public Health Act, 1936, in respect of the health conditions of offices. In view of the procedure laid down by the Act it would not be appropriate for the Minister to recommend minimum standards of working conditions, nor any system of systematic inspection of offices.

Hairdressers Registration Bill.—The Hairdressers (Registration) Bill, which was introduced by Lord STRABOLGI in the House of Lords and read the first time on July 2, provides in Clause 21 that nothing in the measure shall prevent the exercise of any right or function by a registered medical practitioner or a registered chemist which he is entitled to exercise under any other Act. The Bill was introduced in the House of Commons last year, and since then there have been several changes in its provisions. The definition of hairdressing has been extended and the saving for doctors and chemists is a new clause. The date for the second reading debate has not been fixed.

Physical Standard of Recruits.—Replying to Sir Arnold Wilson on July 2 Mr. HORE-BELISHA said the physical standard required of recruits for line regiments was still equivalent to, if not higher than, that for a first-class life insurance policy.

Nursing Homes Registration.—Answering Mr. Rostron Duckworth on July 5 Sir KINGSLEY WOOD said by-laws under the Nursing Homes Registration Act, 1927, had been made by eighty-eight local supervising authorities in England and Wales and by forty-two district councils to which the necessary powers had been delegated. The information available was not sufficient to enable him to state the number of authorities which had not made by-laws. The few complaints received in his Department were normally referred to the local authorities responsible for the registration and inspection of nursing homes, and to which such complaints should properly be addressed.

Health of Mercantile Marines.—On July 6 Mr. CREECH JONES asked the President of the Board of Trade what arrangements existed in his Department for the study and prevention of unhealthy conditions of the mercantile marine; whether any medical officers in his Department were charged with this special responsibility; and to what extent consultation with the Ministry of Health on these matters was a practice of the mercantile marine section of his office. Mr. OLIVER STANLEY replied that there were three medical officers attached to the survey staff and close contact was maintained with the Ministry of Health and the port sanitary authorities. Questions relating to the general health of the mercantile marine were dealt with by an interdepartmental committee of the Board of Trade and Ministry of Health representatives. The plans of ships built in this country were examined, and any necessary steps were taken to ensure that the crew's accommodation conformed to the present standards of hygiene and comfort. Provisions for the maintenance of the accommodation were included in the instructions to surveyors on this subject, which had recently been revised and would shortly be issued. In addition, Board of Trade surveyors took every opportunity to inspect the crew's accommodation on ships in service.

Medical Treatment of "Deutschland" Casualties.—On July 6 Mr. MAGNAY asked the Secretary of State for War whether any charge would be raised against the German Government in connexion with the reception and medical treatment of casualties from the German battleship *Deutschland* in the military hospital, Gibraltar. Mr. HORE-BELISHA replied that no charge would be raised against the German Government in respect of a humane service which would always be readily rendered in such circumstances. The cost would be borne on Army funds.

Cost of Dental Benefit.—Sir KINGSLEY WOOD told Mr. D. J. B. Joel on July 8 that the cost of providing dental benefit as a statutory benefit could not be estimated with precision in the absence of reliable data regarding the number of insured persons who would apply for treatment. Such information as was available indicated that about 10 per cent. would apply for treatment each year at an average cost of about £4 per case. On this basis the cost would be approximately £7,000,000 a year. Dental benefit was provided as an additional benefit by 5,000 approved societies and branches in England and Wales with a total membership of 11,800,000, representing 75 per cent. of the insured population. The expenditure on this benefit in 1936 was about £1,750,000.

Shortage of Trained Nurses and Probationers.—Sir ROBERT RANKIN, on July 8, asked whether the attention of the Minister of Health had been called to the increasing shortage of trained nurses and probationers, and whether, in view of the great expansion of the hospital system and public health services of the country in the last ten years, he could state what steps were being taken to ensure an adequate supply of nurses during future years. Sir KINGSLEY WOOD said he had been informed that there was a shortage of nurses relatively to the increased demands for their services. The matter was receiving his close attention, and the associations representing local authorities were in communication with the General Nursing Council regarding certain measures for meeting the situation. Miss WILKINSON asked if the Minister had called the attention of the voluntary hospitals to the necessity for reducing the hours and increasing the wages of their nurses if they wished to get a sufficient number. Sir KINGSLEY WOOD said many hospitals were doing what they could about this important matter.

Midwifery Schemes in Wales.—Sir KINGSLEY WOOD told Mr. Temple Morris on July 8 that proposals under Section 1 of the Midwives Act, 1936, for a service of salaried midwives had been submitted by all the local supervising authorities in Wales, numbering nineteen. The Minister's formal sanction was not required to these proposals, but in three cases he had informed the authorities that in his opinion their proposals were satisfactory. In these and other cases the authorities were proceeding to put the proposals into operation. In some cases he was still in communication with the authorities.

Housing in Glasgow.—Dr. ELLIOT, replying to Mr. Buchanan on July 13, said that the number of houses in the Gorbals Division being dealt with under the Housing Acts as unfit for human habitation or at present on the Corporation's list awaiting such action was 1,773, and that the corresponding number a year ago was 1,799. The latest available information with regard to the number of over-crowded houses in the division was obtained as a result of the overcrowding survey at the end of 1935, when the number was 7,619. It was not possible to show separately the numbers of houses being built for slum clearance and for the relief of overcrowding, as the Corporation was dealing with these problems together, and the purpose for which particular houses were to be used was not determined till the houses were completed. On June 30, 1936, 2,437 houses were under construction, with State assistance, for slum clearance and the relief of overcrowding, while 1,318 had been contracted for but not begun. On June 30, 1937, 2,637 houses were under construction and 2,080 had been contracted for but not begun. On June 30 last year 250 houses were under construction and 98 had been contracted for, without State assistance, while on June 30, 1937, 202 such houses were under construction.

Mortality of Disabled Pensioners.—Mr. H. RAMSBOTHAM told Mr. W. Thorne on July 14 that the number of ex-service disability pensioners who died in the eight years ended March, 1937, was 56,468. The annual mortality rate was about 15.7 per 1,000 pensioners. Comparative figures were not available for the year ended March, 1930, but during the next seven years the average mortality rate of disability pensioners was 16 per 1,000, whereas that of the general male population of corresponding ages in England and Wales during the same period was approximately 10 per 1,000.

Supervision of Nursing Homes.—Miss RATHBONE asked, on July 15, what report had been made by the local authorities to the circular letter of September 30 last, in which attention was called to the importance of the adequate supervision of nursing homes. Sir KINGSLEY WOOD, in reply, said he had not called for a special report from local authorities on this subject. The circular requested the local supervising authorities to satisfy themselves that their arrangements for the inspection of nursing homes sufficed to ensure that the requirements of the Nursing Homes Registration Act were in all cases fully observed. Sir FRANCIS FREMANTLE: As the right hon. gentleman issues a circular every year advising the medical officers on what they should deal with in their annual reports, will he ask them to pay special attention to this matter, which has hitherto been very considerably neglected in many large areas?

Silicosis Claims.—In response to a request by Mr. James Griffiths on July 15, Sir SAMUEL HOARE furnished the following table:

Applications to the Silicosis Medical Board in the six months ended June 30, 1937, for Certificates under the Various Industries (Silicosis) Schemes

	Applications Received	Granted	Refused or Negative	Awaiting Decision
Death	48	32	14	2
Disablement or suspension	327	130	162	35
Separate particulars for anthracite miners for same period.				
Death	23	14	7	2
Disablement	114	56	45	13

Hours of Work in Ministry of Pensions Institutions.—Mr. KIRBY asked the Minister of Pensions the number of hours a week normally worked by the indoor and outdoor staffs respectively of those hospitals and institutions controlled by his department. Mr. RAMSBOTHAM said that the hours worked weekly by hospital staffs varied with different grades. Nurses' duties varied from fifty-seven to sixty-one hours a week for day duty and seventy-eight hours for night duty, both inclusive of meal times. Massage staff and x-ray assistants attended for thirty-six and thirty-five hours respectively, exclusive in both cases of meal times. Stewards, clerks, and orderlies were employed from forty-four to forty-eight hours, and domestics from forty-eight to seventy-two. The only staff on outdoor duties were orderlies employed as gardeners, ambulance drivers, etc., who were subject to a forty-eight-hour week.

Medico-Legal

DERMATITIS FROM HAIR TREATMENT

A Manchester lady, at the suggestion of her hairdresser, consented to try a preparation called "oloxo" instead of henna. After preliminary treatment "oloxo" was applied to her head, and the next morning she felt a burning sensation which grew worse. Her hairdresser unsuccessfully treated the dermatitis which developed, and then informed the proprietors, Oloxo, Ltd. A representative of the firm expressed great regret and advised the patient to see a doctor. The disease ran a very painful course; her head suppurated and her face became so swollen that she could not see for three days; her hearing was affected, she could not sleep, and a rash extended all over her body. Under treatment by a dermatologist the condition gradually improved. The patient brought an action against the hairdresser and Oloxo, Ltd., claiming damages for negligence, and the hairdresser sued Oloxo, Ltd., for an indemnity.

At the time of the action, which was tried by Mr. Justice Hilbery at Manchester Assizes at the beginning of July,[1] the patient gave evidence that she was still under treatment, could not do her housework, and was nervous and afraid to go out alone. She could not tolerate heat. She said she had paid the hairdresser half a guinea for the treatment and had only undergone it on the express promise that oloxo was harmless and would not affect her. She had general poisoning, and could not recover for at least six months. She had no predisposition to skin disease. The hairdresser testified that she had attended a series of classes given by Oloxo, Ltd., and their representative had assured the pupils that Oloxo was perfectly safe and had offered to indemnify them against claims for damages. She had never been told to make a test. She had used on the patient the method she had been taught.

At the end of the case for the patient and the hairdresser all parties agreed to continue the trial before the judge alone, and the jury was released. Counsel for Oloxo, Ltd., stated that the firm merely marketed oloxo, which was made in the United States. They dealt only with wholesalers and not with hairdressers, though they sometimes held local lectures to stimulate trade. The managing director admitted in evidence that there was always a possibility of danger to abnormal skins. The firm's booklet now advised that each customer should be tested, but at the time of the present accident it had contained no such instructions. The packets now bore a notice saying that the preparation might cause serious inflammation on the skin of certain persons and should be used only in accordance with expert advice. The notice had not been on the package at the time of the accident, but had been put on after consultation with the Home Office about the Poisons Rules. He admitted that he had distributed a preparation which he regarded as dangerous without a test, but had not said that a test should be made in every case. He believed that the hairdresser had been warned to make a test. The lecturer stated that he had always told students to make a test and had never represented oloxo as perfectly safe and harmless.

The learned judge found as a fact that the traveller of Oloxo, Ltd., had told the hairdresser the preparation was safe and that without this assurance she would not have ordered any. He had no doubt that she and the patient had intended that the assurance should be a warranty and an essential term of the contract for the application of oloxo. He came to the conclusion that oloxo was not safe for the purpose for which it was sold and that the company had known it was not safe. The damage to the patient was in the direct line of consequence from the breach of duty committed by Oloxo, Ltd. Nobody could tell without a test whether a customer would suffer or not. As they sold it for application to all heads and gave no warning that it was dangerous without a test, they must be held to be selling an article dangerous in itself. He was satisfied that the representative of Oloxo, Ltd., had assured hairdressers at lectures that the firm would indemnify them against any claim. The firm had gone back on this indemnity and it had not been made at a time when it could be part of the contract with the hairdresser; nevertheless, nearly all the hairdresser's costs had been caused by their repudiating it. He gave judgement for £520 damages for the patient against the hairdresser, and for the hairdresser against the firm.

[1] *Manchester Guardian*, June 30, July 1 and 2.

The Archbishop of Canterbury, speaking at the Mansion House at a festival dinner of the Princess Elizabeth of York Hospital for Children, said that following a gift of £10,000 by Mr. E. W. Meyerstein and an offer by Mr. S. Garton of his family home at Banstead, the new hospital was being built among the Surrey woods. The cost would be about £200,000, of which £70,000 was already available, but £130,000 had still to be raised in the next twelve months unless the work was to stop. Brigadier-General Sir Hill Child, chairman of the hospital, announced donations at the dinner totalling £5,701. The out-patients' department, emergency beds, and the old hospital buildings at Shadwell will be maintained and used as a clearing station. Patients will be transferred by ambulance to the new hospital.

Medical News

By an Order of the Committee of Privy Council, made after consultation with the Medical Research Council and with the President of the Royal Society, L. J. Witts, M.D., F.R.C.P., Professor of Medicine in the University of London and Physician to St. Bartholomew's Hospital, and G. E. Gask, C.M.G., D.S.O., F.R.C.S., Emeritus Professor of Surgery in the University of London, are appointed members of the Medical Research Council, in succession to Sir Thomas Lewis, C.B.E., M.D., F.R.C.P., F.R.S., and Sir David P. D. Wilkie, O.B.E., F.R.C.S., who retire in rotation on September 30.

The third congress of the International Society of Geographical Pathology will be held at Stockholm from August 5 to 7, when various aspects of anaemia will be discussed. Further information can be obtained from Professor F. Henschen, Caroline Institute, Stockholm.

The third International Congress for Medical Postgraduate Instruction will be held in Berlin from August 21 to 24. The meetings will be held in the Langenbeck-Virchow House, Luisenstrasse 58–59. Further information can be obtained from the general secretary, Professor Adam, Kaiserin Friedrich Haus, Robert Koch Platz 7, Berlin, N.W.7.

The King has approved the grant to the Institute of Hygiene of a supplemental Royal Charter giving it power to amalgamate with the Royal Institute of Public Health. The amalgamated bodies will be known as the Royal Institute of Public Health and Hygiene.

The Minister of Health, speaking at the Health Congress of the Royal Sanitary Institute at Birmingham last week, announced that the Prime Minister would inaugurate a National Health Campaign in October in London for the purpose of making the health services better known and getting them better used. The Prime Minister would be supported by leading men in all the parties. The slogan of the campaign would be "Use Your Health Services." There would also subsequently be meetings in large and small towns addressed by prominent men and women, and it was hoped to enlist the press, the wireless, and the films.

Dr. F. Murgatroyd, of the Liverpool School of Tropical Medicine, who is at present engaged on research work on sleeping sickness in West Africa, has recently been appointed assistant physician to the London Hospital for Tropical Diseases.

Dr. G. Jessel has been elected president of the North Western Tuberculosis Society after 18 years' service as hon. secretary. Dr. A. Fleming (11, Woodvale Road, Knutsford, Cheshire) has been appointed hon. secretary in succession to Dr. Jessel.

At the July meeting of the Central Midwives Board for England and Wales appointment as examiner was granted to Dr. Charles Henry Walsh; and Wellhouse Hospital, Barnet, and Park Hospital, Davyhulme, Manchester, were approved as institutions for providing instruction in the essentials of obstetric analgesia and in the use of a recognized apparatus.

The May issue of the *Bulletin de l'Office International d'Hygiène Publique* contains articles on malaria in Southern Serbia, sanitary and medical investigations in the Liberian Republic in 1935 and 1936, determination of blood groups, the campaign against contagious abortion in cattle in Norway, destruction of grasshoppers, and arsenical poisoning in workers.

By Wednesday afternoon 1,150 members had registered their attendance at the Annual Meeting of the British Medical Association in Belfast this week.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Finance Department, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Finance Department.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

QUERIES AND ANSWERS

Health Services in Holland

Dr. CHRISTOPHER ROLLESTON (Ketton, Stamford) writes: I have been looking at the statistics of the League of Nations and find that Holland is apparently the healthiest country in the world. The infant mortality rate is 34 per 1,000; pulmonary tuberculosis mortality 0.4, and so on. Is this well known to the profession in this country? If so, how is it explained? I have known for some time that their child-bearing figures are good, and I understand that their medical curriculum is longer than ours. What I am anxious to know is whether the health services in Holland have been developed extensively.

Agranulocytosis and Rheumatism

Mr. L. A. RIDDELL, F.R.C.S. (Redruth) writes: I should like to ask a question relevant to the paper by Dr. C. J. Young on "Agranulocytosis and Para-amino-benzene Sulphonamide" (*Journal*, July 17, p. 105). Has any connexion been noticed between rheumatic conditions and agranulocytosis or relative polymorphonuclear leucopenia, irrespective of the treatment given?

Income Tax

Liability to U.K. Tax

"D. B." lives most of his time in Ireland, but since July, 1936, following a postgraduate course, he has done locumtenent work in the United Kingdom. He intends to live either in Ireland or England according to the location of a suitable appointment. Is he liable to pay the United Kingdom tax or to be taxed by the Irish Free State?

*** He is liable to account for tax on his earnings here to the authorities in the Irish Free State until such time as he becomes resident—as distinct from occasionally resident in the United Kingdom—when he will become liable to tax in this country.

Commencing Employment

"ASSISTANT" had a hospital appointment from May, 1936, at £175 per annum "all found." He held it until August 13, 1936, earning (cash) £42, and then began as an indoor general assistant at £350 per annum, car and expenses provided. That terminated at May 8, 1937, and after a week's interval he took another appointment at £350 (indoor) plus an allowance of £50 for car expenses. What is his liability?

*** For the financial year ended April 5, 1937, he earned £42 + £225 = £267, and that is the gross amount of income for which he is assessable for 1936-7. As regards 1937-8 he will be assessable on the amount of his earnings for that year, and the declaration of income can be deferred until after April 5, 1938. In calculating his earnings from his

present employment he can either ignore the £50 car allowance or include it, and then deduct the running costs and depreciation of the car, but not instalments of purchase price, as they are capital outlay. As the assessments for each year will presumably be made after the financial year is over, the whole tax for that year will become due a few weeks after the assessment is made.

Gratuity on Leaving R.A.F.

"A. C. C." will be entitled to a gratuity of £1,000. Will this be subject to income tax if used to purchase a practice?

*** Payments made by way of gratuity to civil servants on retirement are not taxable, and we see no reason why similar treatment should not apply to an R.A.F. gratuity payable after only five years' service. "A. C. C.," however, might put the point to the assessing officer of the R.A.F. so that he would have an authoritative statement for future reference. The use to which the gratuity is put should not affect the question of taxability.

General Expenses—Rent, Rates, etc.

"A. C." refers to a table of expenses given in Professor A. L. Bowley's memorandum with regard to the Court of Inquiry's investigation into the capitation fee, and points out that two-thirds is included in the table for rent, rates, fuel, and light, whereas he has claimed only one-third for income tax purposes.

*** "A. C." has apparently misunderstood the nature of the expenses in the table—they refer to private, not professional, expenses. Consequently the two-thirds shown in the cost-of-living statement is consistent with the one-third which he has treated as a professional expense.

Payment for Guaranteeing a Loan

"R. D." refers to a previous reply on the above question—presumably one in our issue of December 8, 1934—and encloses a letter from his inspector of taxes which admits that the point is not covered by case law, but argues against allowing the deduction.

*** The statement of facts in the case of Ryall *v.* Hoare supports the view that when that case was taken to the High Court the Revenue had allowed the borrower to deduct the guarantee payment as an expense. But that fact was not relevant to the decision and the case has accordingly no validity as authority for the allowance. The chief difficulty is that the payments arise out of the financial position of the practitioner and not out of the circumstances of the practice, and this lends some support to the view that they are "capital" expenses and not incurred in carrying on the practice. In the absence of judicial direction the point is in doubt, and on its merits we are not prepared to advise "R. D." to take it to formal appeal.

Production of Balance Sheet

"E. S." has a sale practice and the inspector of taxes is "demanding" production of a balance sheet for the practice. Is this in order?

*** In our experience such requests are rare in the case of professional practices (where the amount of assets used in the work is usually relatively small) and is certainly not made where the assessments have been on the cash receipt basis. We suggest that our correspondent might point this out to the inspector and inquire for what special reason a balance sheet is required in his particular case.

Allowance for Bank Interest

"X. Y. Z." was unable to claim the special allowance for bank interest paid by him in the years ending April, 1931, 1932, and 1934 as his "profits were not large enough to be assessable." Can any allowance now be claimed for 1936–7 and 1937–8?

*** Only in respect of interest paid in those years. It has to be remembered that each financial year stands by itself, and relief for interest paid in any one year is due only against tax payable for the same year. (Where the interest can be treated as an "expense" it affects the following year, but in the long run the result is normally the same.)

LETTERS, NOTES, ETC.

Rheumatism and Influenza

Dr. F. E. GRAHAM-BONNALIE, the director of the Brighton Rheumatism Clinic, writes: With reference to the correspondence which has been appearing in your columns (*Journal*, June 26, p. 1352) regarding the incidence of influenza, during the last winter, among patients being treated with the Warren Crowe rheumatic vaccine, the following figures may be of interest to your readers. Of 138 people who have been interrogated this week and who had been receiving the vaccine treatment, twenty-four had influenza and 114 remained free. In the case of the 114 who remained free, there were twenty cases of influenza in their homes. Whether these figures afford any evidence of immunity conferred upon these patients would appear to depend upon the influenza incidence among the general population.

Droitwich Spa

Medical men who wish to advise special treatment for their patients do not always have ready at hand details about the facilities, social and medicinal, of the various spas in this country. We have recently received a well-illustrated pamphlet entitled *Droitwich Spa and the Treatment of Rheumatism*, in which full information is given of the therapeutic equipment available at Droitwich, an analysis of the water, and other information of use to the prospective patient and to his practitioner. It can be obtained by medical men free of charge on application to the Spa Director, Droitwich, Worcestershire.

Medical Golf

The Scottish Medical Golfing Society held its summer week-end meeting at Princes' Golf Club, Sandwich, on July 10 and 11. The results of the competitions were as follows. Singles *v.* Bogey: 1, Dr. Bruce Williamson (12) 3 down; Sir Lancelot Barrington-Ward, Drs. Bertram Shires, Keith Forbes, Desmond Curran, and Walter Maclay tied for second place with 4 down. Four Ball *v.* Bogey: 1, Drs. Bartleman and Curran, 5 up; 2, Drs. Maclay and Gordon, and Drs. Bruce Williamson and Keith Forbes tied at 3 up. The Medal Round was won by Dr. Curran (7), 73; Dr. Donald Paterson (18) was second with 75, and Mr. Rupert Scott (9) third with 76. The Silver Haggis for the best eclectic score was won by Dr. W. A. Low with 68 (86 less 18). In addition to the above there were various hidden prizes.

Digest of Treatment

In the *Journal* of July 10 (p. 73) we announced the appearance of a monthly review of therapeutics entitled *Digest of Treatment*. This is published by J. B. Lippincott Company, Washington Square, Philadelphia, but in this country the annual subscription of 25s. and any inquiries may be addressed to J. B. Lippincott Company, 16, John Street, Adelphi, London, W.C.2.

Corrigendum: One-eyed Pilots

Mr. J. MYLES BICKERTON'S letter on page 138 of our issue for July 17 contains an error which renders the table useless. The second column, group 3, should have read "6/6 or 100 per cent., *with* glasses." The table is here reprinted in its correct form:

Standards for One-eyed A Licence Pilots

Group	Good Eye	Other Eye
(1)	6/6 vision or 100 per cent., without glasses Normal field of vision Not colour blind	Blind Standard (Group 1 or Group 2 or Group 3)
(2)	6/9 or 90 per cent., without glasses Normal field Not colour blind	6/60 to 6/24 (with or without glasses) Field good
(3)	6/6 or 100 per cent., with glasses Normal field Normal colour vision	6/24 with correction Field good Binocular vision

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

62 Vitamin C in Haemoptysis

F. CAPELLI (*Riv. Patol. Clin. Tuberc.*, May 31, 1937, p. 317) has found ten daily intravenous injections of 50 milligrammes of ascorbic acid useful in certain haemoptyses due to pulmonary tuberculosis in a small series of patients. The method failed in two cases of haemorrhage accompanying a new extension of the tuberculous process proved radiologically, but it appeared strikingly successful in the prevention of regularly recurring haemorrhages in cases of long-standing fibrosis with cavitation, and it seemed effective when other treatments failed in cases of frequent small haemoptyses in those having minimal pulmonary foci of infection. In phthisis there is little alteration of the blood coagulation rate, and the haemostatic action of vitamin C would appear to be attributable to a regulatory effect on adreno-cortical and anterior pituitary hormones, combined possibly with a catalytic action on clotting ferments.

63 Zinc Fever

H. NATVIG (*Tidsskr. norske Laegeforen.*, May 1, 1937, p. 457) has investigated, under the auspices of the University Hygiene Institute in Oslo, the conditions in which zinc fever arises. It is due to the inhalation of particles of zinc oxide by workers in factories where zinc-containing metallic compounds are made. The author had no difficulty in finding more than 100 workers with a characteristic history of symptoms which overtook them only after they had left work and had reached home, and which consisted of headache, lassitude, shivering, an unpleasantly sweet taste, hoarseness, a sore throat, smarting in the eyes, and a sense of oppression in the chest followed in a short time by a rigor, with a temperature of 104° or more. After about two hours the patient would feel a pleasant sense of warmth followed by profuse sweating. As many as thirty-six patients had had one or more such attacks every week, some for several years. In every brass foundry inspected by the author in the course of two and a half years he has observed cases of zinc fever. In some works various precautions had been taken, including the installation of fans and the wearing of masks, but none had proved effective. Natvig concludes that the only successful method of prevention is to remove from the air breathed by the workers the particles of zinc oxide as soon as they are generated by the contact of vaporized zinc with the oxygen in the air. He has devised a movable funnel with a fan, which aspirates the zinc oxide as soon as it is produced.

64 Chronic Fibrous Adhesive Pericarditis

H. C. A. LASSEN (*Ugeskr. Laeg.*, May 27, 1937, p. 567) has compared the clinical records with the findings at necropsy on fifty-seven cases of chronic fibrous pericarditis observed in a Danish hospital between 1922 and 1934. During this time 1,601 medical cases came to necropsy, and the fact that from 2 to 3 per cent. of them showed adhesive pericarditis suggests that this condition is by no means rare. Thirty-two of the patients were men and there were only ten under the age of 40; as many as thirty-one were over 60. There was a record of rheumatic fever in twenty cases, and in only three had pericarditis been diagnosed before death. In seven cases tuberculosis of the lungs found post mortem had not extended to the pericardium, but there was one case of tuberculous mediastino-pericarditis without involvement of the lungs. In as many as forty-nine cases no tuberculosis could be found. Nine patients suffered from syphilis, and in forty-four cases the Wassermann reaction had been negative. Thirty-six of these patients were under weight. In twenty-nine cases some cardiac murmur had been detected, and in only seven cases had there been no signs or symptoms before death of heart disease. The author has come to the conclusion that in not one of these cases could operative treatment have achieved any success considering the extent and severity of the lesions found at necropsy.

65 Reinfection in Scarlet Fever

V. D. ALLISON and W. A. BROWN (*J. Hyg.*, Camb., April, 1937, p. 153) define the term reinfection as the secondary infection while in hospital of a scarlet fever patient with *Streptococcus pyogenes* of a serologically different type from that producing the first infection. Of forty-seven scarlet fever patients nursed in a multiple-bed ward and swabbed twice weekly, thirty-three (70.2 per cent.) became reinfected. In fifteen of these the reinfection gave rise to no clinical signs, while in the remaining eighteen it was accompanied by clinical signs or complications. Patients in cubicles or in wards containing cases of a single serological type did not show either reinfection or such complications. Most of the complications were due to reinfection, which occurred in the third week when patients were convalescent. Most commonly reinfection was by the direct contact of patient with patient. The writers suggest that scarlet fever patients should be nursed in separate cubicles, or at least by the bed-isolation method in multiple-bed wards.

66 Diphtheria Carriers

M. MITMAN (*J. prev. Med.*, May, 1937, p. 249) states that a large number of individuals carry diphtheria bacilli temporarily; they are no danger to others and are developing their own immunity. He therefore deprecates the unsystematic hunting out of carriers by indiscriminate swabbing, and regards it as more practical to make local conditions the sole criterion for such investigations. He urges that in every carrier and in every doubtful case of diphtheria virulence tests and Schick tests should be performed for the purpose of classifying and of separating all carriers.

Surgery

67 Endocrine Treatment of Breast Conditions

DESMAREST and CAPITAIN (*Presse méd.*, May 26, 1937, p. 777) point out that recently efforts have been made to trace a connexion between ovarian dysfunction and the various diseases of the mammary glands. Lesions of the breast range in severity from simple congestion, which often precedes menstruation, to lesions of the connective and epithelial tissues. Massive glandular hypertrophy and the development of chronic mastitis are benign lesions, but it is not known to what extent they contribute to the later development of malignant disease. Opinion differs as to the treatment of these breast lesions, but the authors consider that, while an unnecessarily mutilating operation should be avoided, some limited form of operative treatment is perhaps advisable in cases of large and painful cysts. Generally, however, surgical excision has now largely given place to treatment by intramuscular injections of acetate of testosterone, a male hormone which has been isolated from the testicles of bulls. Particulars are given of seventeen cases which included instances of congestion, hypertrophy, nodular glands, and cystic degeneration. These patients were all treated by injections of testosterone, and there was only one failure which occurred in a woman of 47 years who had suffered for

a long time from bilateral Reclus's disease. It is suggested that testosterone acetate may be of value in the relief of pre-menstrual congestion, in preventing the development of chronic mastitis, in bringing about the diminution and disappearance of adenomatous nodules, and in relieving pre-cystic disease of the breast. In cases in which the cyst is large puncture should precede injection, and the authors believe that this procedure will eventually take the place of mutilating operations in the treatment of cysts occurring in young women.

68 Osteoporosis Circumscripta

H. H. KASABACH and A. B. GUTMAN (*Amer. J. Roentgen.*, May, 1937, p. 577) review forty-seven cases of osteoporosis circumscripta of the skull and discuss its relationship to Paget's disease of bone. The affection usually begins with the appearance of small rounded circumscribed areas of osteoporosis, often in the frontal region near the base, sometimes in the occipital region, and occasionally elsewhere. These areas expand over a period of years until the major portion of the calvarium or the entire calvarium is involved. Often several foci appear independently in both the frontal and occipital regions, and as the process extends they become confluent. Since the initial foci originate near the base the last remnant of normal bone is most likely to be in the parietal region posterior to the vertex, producing a characteristic design in the lateral radiograph of the skull. In thirty-two out of the forty-seven cases osteoporosis circumscripta of the skull was associated with Paget's osteitis deformans affecting bones other than those of the skull. In eighteen cases the skull was the site of both osteoporosis circumscripta and the "cotton-wool" shadows characteristic of Paget's disease. In the majority of cases there were no clinical symptoms, but in some cases there was headache, vertigo, migraine, and epileptiform attacks. In seventeen out of eighteen cases in which chemical analyses of the blood were carried out the serum calcium and inorganic phosphorus were within normal limits. Pathological examination of the affected bone revealed a condition identical with that described by Schmorl under the name of "haemorrhagic infarction of the calvarium." In seven cases the osteoporosis circumscripta of the skull was associated with tumours of the maxillary bone, and in all these cases the adjacent frontal bone was the site of the osteoporosis.

69 Deep Infection of the Neck

L. C. BOEMER (*Arch. Oto-laryng.*, Chicago, April, 1937, p. 465) reviews seventy-five cases of deep infection of the neck, twenty-six in adults and forty-nine in children. There were two deaths in the series, both among the adults. One was a woman, aged 22, who had a peritonsillar abscess complicated by jugular bulb thrombosis and osteomyelitis of the sphenoid bone, and who died from basal meningitis. The other fatality was due to complications following a neglected chronic purulent mastoiditis. At necropsy thrombophlebitis of the lateral sinus and of the internal jugular vein were present, and there was also extensive erosion of the wall of the internal carotid artery without actual rupture. An extension of infection from the lower third molar accounted for the condition in one-third of the adult cases. Suppuration of the retropharyngeal glands or of the deep cervical glands accounted for it in the forty-nine children, and they all recovered. The great danger is an infection of the pharyngomaxillary and parapharyngeal spaces with involvement of the great vessels of the neck. Early adequate drainage by external incision is necessary, and the author recommends thorough exploration through a T-shaped incision, the main surgical landmarks being the greater horn of the hyoid bone and the tip of the styloid process. The great vessels must often be followed upwards to the base of the skull and downwards along the whole extent of the carotid sheath.

Therapeutics

70 Ammonium Mandelate in Urinary Infections

C. L. DE JONGH (*Nederl. Tijdschr. Geneesk.*, June 12, 1937, p. 2721) records his observations on twenty patients, fourteen of whom were suffering from simple pyelitis and six from pyelocystitis, treated by ammonium mandelate in doses of 12 grammes daily. The best results were obtained in the cases of chronic relapsing *B. coli* pyelitis in which the temperature was below 102.2° F. The drug is contraindicated when the renal function is defective, and the results were unsatisfactory in the presence of retention of urine.

71 Intravenous Caffeine

R. MARTINETTI and A. FORCONI (*Policlinico*, Sez. Med., June 1, 1937, p. 286) record their observations on the effects of the intravenous injection of caffeine sodium benzoate in twenty-six patients. There were fourteen cases of hypertension, one of diabetes mellitus, and one of diabetes insipidus, while ten were normal from the renal, circulatory, and metabolic points of view. The doses ranged from 0.24 to 0.48 gramme, and the results were as follows: (1) There was a rise of the systolic blood pressure, most marked in cases of hypertension, immediately after the injection, with a rapid return to the original level; (2) there was immediate but transient tachycardia, most pronounced in the cases with hypertension; (3) in the cases with hypertension a slight degree of hyperglycaemia was frequent; and (4) there was an increase of diuresis with a greater elimination of urea and chlorides than usual.

72 Acetyl-beta-methylcholine

A. MYERSON, P. G. SCHUBE, and M. RITVO (*Radiology*, May, 1937, p. 552) have studied the effect of acetyl-beta-methylcholine (mecholyl) on the tone and motility of the colon. Tone and motility were both definitely increased in every case, though the effects were rapidly abolished by atropine. The authors suggest the possibility of using mecholyl in the treatment of atony of the colon.

Dermatology

73 Lupus in Brazil

J. RAMOS E SILVA (*O Hospital*, Rio de Janeiro, May, 1937, p. 569), who records a personal case, states that lupus vulgaris is excessively rare in Brazil. According to H. Portugal only eight examples were found among 3,183 dermatological cases selected for their rarity. Although it is rare to meet with cases of lupus in sanatoria and dispensaries for tuberculosis, the proportion of cases with concomitant pulmonary tuberculosis is fairly considerable—namely, 30 per cent. (Bruusgaard), 21.5 per cent. (Martenstein), and 42 per cent. (Volk). According to the recent investigations of Funk, which confirm previous researches, lupus is caused by bacilli of the human type in 78.4 per cent. and by those of the bovine type in 21.6 per cent. Before the age of 20 the proportion of the bovine type is higher—44.4 per cent.—and this is attributable to milk-borne infection. Up to the age of 16 Griffith found the bovine type in 52.9 per cent. Cases due to the avian type of tubercle bacillus are extremely rare, one having been recorded by Saenz and another by Nicolau and Blumenthal. The number of tubercle bacilli in the lesions is always small, and they are difficult to detect. Inoculation of guinea-pigs is occasionally unsuccessful. The highest proportion of successful results is obtained by Lowenstein's medium. The nasal mucous membrane appears to be the most accessible portal of entry of infection, which accounts for the high proportion of localizations in the centre of the face. In 59 per cent.

of Funk's cases the initial lesion was found in the nose. Silva's case was that of a youth, aged 19, who was the subject of congenital syphilis, with lupus of the nose and face of the ulcero-vegetative type.

74 Dermographism

E. DICKER (*Brux. méd.*, June 13, 1937, p. 1212) points out that dermographism following external stimulation is due to a triple response of the cutaneous capillaries—namely, vasoconstriction, vasodilatation, and the appearance of oedema. Clinically several types are recognized occurring alone or in combination with one another. Dermographism may occur in the form of red or white wheals, erythematous zones, or large elevated areas. All the types have in common a latent period between the stimulation and the reaction, and none of them are pathognomonic of any condition. Dicker believes that dermographism is the result of a non-nervous reflex, and he argues that after a nervous reflex the latent period would be short and always of the same length. In this condition, however, the latent period is relatively prolonged and varies in each individual or in the same person at different times. Further, the latent period lasts longer in individuals with dysfunction of the endocrine glands, such as hyperthyroidism, than in normal persons. The author admits that, although dermographism may occur in areas to which the nerve supply has been cut off, the nervous system may help to produce it, for in hemiplegics the latent period is prolonged on the affected side. It has been shown experimentally that body cells at rest are in a state of electrical equilibrium, but that stimulation of them brings about a change of the potential, and also in the permeability of the cells, and it allows substances normally retained by them to pass through. According to Dicker it is this fact which accounts for the presence of oedema in dermographism and for the dilatation of the capillaries due to a substance similar to histamine called "H." He points out that the effect of stimulation on the cells resulting in a change of electrical equilibrium and permeability must be considered as a general process governing the formation of all inflammatory exudates, and possibly as explaining the occurrence of albuminuria.

75 Dermatomyositis

T. M. GREENAWAY and C. G. LAMBIE (*Brit. J. Derm. Syph.*, May, 1937, p. 209) report two cases of dermatomyositis observed at the Royal Prince Alfred Hospital, Sydney, both of which showed a remarkable similarity of symptoms and died within two years of the onset of the disease. All kinds of treatment were tried without avail. A striking feature in both cases was the heliotrope discoloration of the upper lids. The patients presented oedema of the face and limbs, and weakness, tenderness, and finally wasting and contracture, chiefly of the limb flexors. All the lesions were remarkably symmetrical. The rash was of the erythematous type with extensive scaling. The authors have been unable to discover the cause of the affection, and all available tests showed that the disease had no nutritional or allergic basis. No micro-organism could be found in the blood or affected tissue, and an attempt to discover a virus by animal inoculations proved fruitless.

76 Cutaneous Tuberculosis

H. A. MANIAR (*Med. Bull.*, May 15, 1937, p. 296), who reviews tuberculous conditions of the skin, finds that miliary tuberculosis is rare and particularly affects children. It occurs as a papulo-vesicular rash with scale or crust formation, and biopsy proves its nature; the prognosis is bad. Tuberculosis cutis orificialis occurs as an acute ulcer in patients with visceral disease. The ulcers, which are painless and do not tend to heal, are shallow with thin undermined edges, circular in outline and with enlarged neighbouring glands. Radiotherapy is valuable in this condition. Verruca necrogenica is due to direct inoculation of the tubercle bacillus. Creosote and 33 per cent. salicylic acid plasters or *x*-ray exposures, followed by radiotherapy, are useful. Scrofulodermia is treated surgically, the infected glands and skin being widely removed. Skin grafts may be required when primary union is impossible. In the treatment of chronic tuberculous ulcers the part should be kept at rest and antiseptic dressings applied. Small repeated doses of *x* rays aid healing. In the treatment of lupus vulgaris Maniar advocates Gerson's diet, which is poor in common salt and rich in vitamins and minerals. He believes that ultra-violet-ray therapy over the whole body as well as directly to the lesions offers the best hope of cure. Radium and *x*-ray exposures, freezing with carbon dioxide snow, creosote and salicylic plasters, and painting the lesions with caustics are possible measures. Chemotherapy and surgical intervention are now out of date. In all cases of tuberculosis of the skin general treatment of the condition must never be neglected.

77 X-Ray Carcinogenesis

S. LABORDE (*Rev. Physiothér.*, March–April, 1937, p. 89) points out that although the occurrence of cancer in radiologists has long been known, cases of cancer formation following the therapeutic administration of *x* rays are infrequent owing to the fact that patients are rarely subjected to graduated applications over a sufficiently long period. He reports four such cases occurring eleven, fifteen, eighteen, and twenty-one years after treatment, and in all of which histological examination showed a spino-medullary epithelioma. The first case had had numerous applications over a period of four years for eczema of the hands, the second several applications for hair on the face, the third *x*-ray administration to the spinal column for paraplegia, and the fourth fifteen applications over two years for facial angioma. The first patient was cured by amputation, the second by three applications of radium, the third is becoming worse in spite of radium therapy, and the fourth died. Laborde points out (1) that chronic radio-dermatitis produced by whatever type or quality of irradiation is a precancerous lesion; (2) that although the causal factor after a long latent period was in each case *x*-ray administration, nothing is known of the nature of the phenomenon which suddenly produces malignant growth in tissues, modified in structure and physiology after so many years; (3) that cicatrization and cure may follow the application of radium provided that the cancer is surrounded by sufficient healthy tissue, for the radio-sensitivity of cancers depends on the action of the rays on the neoplastic cells and on the medium in which they develop.

78 Eczema from Trees and Shrubs

V. GENNER and P. BONNEVIE (*Nord. med. Tidskr.*, May 29, 1937, p. 847) consider that when epicutaneous tests are carried out in a search for the cause of any obscure case of eczema the leaves of certain trees and bushes should be examined. They record in detail certain cases in support of this suggestion. One of their patients was a night watchman, aged 35, on whose face and hands eczema had recurred for some years every summer, disappearing again in the winter. At the hospital he attended his condition was regarded as the effect of sunlight, and it was not until epicutaneous tests with the leaves of various trees, bushes, and plants were carried out that he was found to be sensitive only to elm leaves, and it was then learnt that during his night rounds he had to brush through a tangle of elm boughs. The authors have tested sixty-seven patients, most of whom suffered from various forms of eczema, with elm leaves, and they found as many as seventeen who gave a positive epicutaneous reaction, usually within forty-eight hours. The reaction varied in severity, and consisted in some cases only of redness. In others papules appeared or there was slight infiltration. In another of the authors' patients eczema was traced to magnolia leaves.

Obstetrics and Gynaecology

79 Spontaneous Symphysiolysis

G. SCHAAP (*Nederl. Tijdschr. Geneesk.*, May 29, 1937, p. 2510), who records an illustrative case, states that spontaneous symphysiolysis is a very rare occurrence. Wishne and Mayer quote three series of statistics according to which it was seen only once in 30,000 deliveries, four times in 80,000, and three times in 94,000. During pregnancy, owing to the increased blood supply in the pelvis, the ligaments of the different joints become loose, so that an increased mobility of the symphysis and sacral joints develops, and the symphysis can be moved 5 mm. in a horizontal and vertical direction. The symptoms are as follows: (1) There is pain in the symphysis and lower part of the back, sometimes radiating down the thighs; (2) the patient is unable to lift or move the legs, and (3) she has a waddling gait. These symptoms are so characteristic that the diagnosis can be made without *x*-ray examination. Treatment should always be conservative, consisting of absolute rest in bed for four to six weeks according to the severity of the case. Schaap's patient, in whom spontaneous symphysiolysis occurred during delivery, was a woman, aged 25, in whom spontaneous necrosis had occurred in the mesial sesamoid bone of the left hallux a year previously.

80 Genital Malformations

H. HUBER (*Zbl. Gynäk.*, May 22, 1937, p. 1229) draws attention to the combination of genital malformations with malformations of the uropoietic system. In every instance of genital malformation, therefore, the kidneys and ureters should be investigated. The author describes the case of a woman of 23 in which a laparotomy revealed the absence of half the uterus, the corresponding tube, the ovary, and the broad and round ligament. Further investigation revealed the absence of one kidney and of its ureter. The correlation of these anomalies is of importance in view of a possible renal insufficiency in case of pregnancy.

81 Perforation of the Uterus

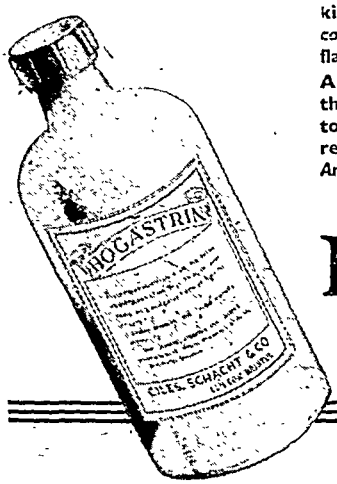
M. MOLNÁR (*Zbl. Chir.*, May 29, 1937, p. 1270) describes two cases of perforation of the uterus; one which was the result of an attempted criminal abortion, while the other was due to the use of a ball forceps for emptying the uterus following an abortion provoked by quinine. In both cases the perforation was covered up by a loop of the small intestine. In the first instance symptoms of perforation with peritonitis appeared five days after the rupture, and in the second ileus developed three days afterwards.

Pathology

82 Vitamin Toxicology

K. SCHÜBEL (*Med. Welt*, May 22, 1937, p. 705) draws attention to the fact that certain of the known vitamins are very toxic and give rise to hypervitaminosis when given in large doses. Hypervitaminosis A has not yet been reported in human beings because the therapeutic range of vitamin A preparations is great. It has been produced in rats and guinea-pigs, however, giving rise to lowered metabolism, haemorrhagic rhinitis, conjunctivitis, diarrhoea, and cramp The daily administration of yeast, 0.5 to 1 gramme, hinders the loss of weight; vitamin C inhibits hypervitaminosis A, and thyroxine causes the symptoms to disappear. Hypervitaminosis B, while not occurring in humans, has been noted in experimental animals, giving rise to such mild symptoms as anorexia, increase of the *p*H of the urine, and a certain minor nervous phenomena. Hypervitaminosis C does not exist, for this vitamin is rapidly eliminated through the kidneys even when large doses are administered. Vitamin D is definitely toxic when given in large doses, and Schübel points out that the therapeutic dose is very little less than the toxic dose. In experimental animals anorexia, loss of weight, diarrhoea, hypercalcaemia with coexisting demineralization and finally death occurred after the administration of toxic doses. Post mortem extensive calcification of the blood vessels, the heart muscle, the kidneys, and the stomach was found, and atrophy of the liver and thymus was noted. The animals were usually sterile, but in some hypervitaminosis was hereditary and the offspring malformed and dwarfed. In those with hypervitaminosis D there appeared to be an increased tendency to malignant tumour formation. Several cases of hypervitaminosis D in children have been reported, though children suffering from rickets are apparently the most immune. The administration of large doses of vitamin B compensates for toxic doses of vitamins A and D. Loss of weight following the administration of vitamin D may be prevented by the administration of vitamins B and C. Vitamin A prevents the occurrence of hypervitaminosis D. Vitamin D is eliminated through the bowel, but not the kidney. Damage to the blood vessels through hypervitaminosis D is progressive even when the doses are discontinued and other attempts are made to overcome the toxic symptoms. In view of this fact and of the widespread use of vitamin D products the author advocates the greatest care in its administration.

83 Bone Marrow Sampling



G. L. WELLER (*J. Lab. clin Med.*, April, 1937, p. 752) describes a method of sampling the sternal bone-marrow by means of a No. 18 gauge spinal needle, which has the advantages over trephining in that it is easy, requires little healing, and can be repeated as desired, and over aspiration in that it avoids admixture with blood. The skin and periosteum over the lower sternum are anaesthetized and the spinal needle with the stylet in place is inserted into the manubrium. When the marrow cavity is entered the stylet is withdrawn and the needle pushed in for about 0.5 to 1 cm. further, after which the needle is withdrawn. Following withdrawal the sample of marrow is pushed to the point of the needle by means of the stylet, and smear films are prepared on glass slides for fixing, staining, and examination. Alternatively the sample can be fixed and sectioned.

84 Serum Cholesterol in Peptic Ulcer

F. M. OFFENKRANTZ and F. FERARU (*J. Lab. clin. Med.*, May, 1937, p. 780) have studied the total and free cholesterol content of the serum in fifty-nine cases of peptic ulcer, of which seven were gastric and fifty-two duodenal, in forty-five male and fourteen female patients whose ages ranged from 22 to 71 years, forty-six of them being between 30 and 50. All the cases examined radiographically showed either deformity of the mucosa or an ulcer crater. Blood samples were collected after a minimum of ten hours' fasting and the serum cholesterol value determined by a modification of the method of Schoenheimer and Sperry. The authors found a mean serum total cholesterol content of 160.8 $\pm$ 38.7 mg. per 100 c.cm. with a range of 98.1 to 300 mg. per 100 c.cm., compared with Sperry's values for normals of a mean of 209.8 $\pm$ 48.6 and a range of 131.5 to 392 mg. Tested statistically, the values for the serum total cholesterol content in cases of peptic ulcer were significantly lower than the normal. There was also a higher proportion of free cholesterol, showing that the fall in the total value was due in greater measure to the decrease in ester cholesterol than to the fall in uncombined cholesterol. The authors were unable to find factors in individual cases that would consistently account for the values obtained therein, but they inferred that the lowering of the cholesterol values in the cases studied was related to the occurrence of ulceration.

In Pernicious and Post-operative Anæmias...

A palatable liquid extract of hog's stomach containing *Hæmopoietin* in stable solution.

The stomachs are treated immediately after killing to extract the *Antianæmic Factor* in active condition producing a bland liquid of pleasant flavour—HOGASTRIN.

A dose of two teaspoonfuls in a little water three times a day for a fortnight, then reduced to one teaspoonful, will invariably give good results in the treatment of all *Macrocytic Anæmias.*

Packed in 4 oz., 8 oz. and 16 oz. bottles.

HOGASTRIN

For inspection sample and literature apply to the manufacturers:—

GILES, SCHACHT & CO.

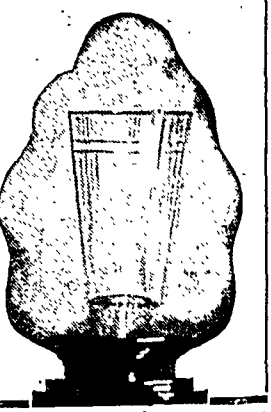
Choose a Spa in Czechoslovakia...

The Spas and Health Resorts of Czechoslovakia, with their centuries-old tradition of healing, reinforced by the experience and researches of local specialists, invite your serious consideration.



In addition to places of world-wide repute such as

PISTANY (Piestany) **CARLSBAD** (Karlovy Vary) **MARIENBAD** (Marianske Lázne) **FRANZENSBAD** (Frantiskovy Lázne)

ST. JOACHIMSTHAL (Jachymov) **TEPLICE-SANOV** (Teplitz-Schönau) **LUHAČOVICE** **SLIAC** **TRENČIANSKE-TEPLICE**

with their medicinal springs and mud baths, there are numerous smaller spas and health resorts admirably equipped for the treatment of many diseases, including those in the following groups:

ANAEMIA AND CHLOROSIS.
BASEDOW'S DISEASE.
BRONCHIAL CATARRH.
CONSTITUTIONAL DISEASES, SCROFULA, RICKETS.
DIGESTIVE DISEASES.
DISEASES OF THE BLADDER AND URINARY ORGANS.
DISEASES OF THE KIDNEYS.
DISEASES OF THE NOSE AND THROAT.
DISEASES OF WOMEN.
DISORDERS OF BONES, MUSCLES, AND JOINTS.
DISORDERS OF THE HEART.
DISORDERS OF METABOLISM AND GOUT.
GALLSTONES.
LEUCAEMIA.
NERVOUS DISEASES AND POST HEMIPLEGIC CONDITIONS.
TUBERCULOSIS OF THE LUNGS.

The arrangements in the bath establishments are up-to-date in every way, the cleanliness and neatness proverbial, the service attentive and courteous.

It is accepted that a spa cure to be fully beneficial should provide a complete change of surroundings, and a break with the patient's normal everyday life.

The Czechoslovak Spas fulfil this purpose admirably . . . comfortable hotels . . . first-class orchestras and dance bands . . . every facility for sport—tennis, golf, swimming, riding, fishing, etc.

There are also numerous fully up-to-date homes for convalescence and rest cures.

Salary at the rate of £300 per annum, together with board, etc., valued at £150 per annum. These appointments are limited to twelve months.

The officers appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by them.

It is not feasible to attend classes for the D.P.H. in conjunction with these appointments.

Forms of application may be obtained from the Medical Superintendent, Dr. J. McGarrity, Little Bromwich Hospital, Birmingham, 9, and should be returned to him on or before July 31st.

The Council House, F. H. C. WILTSHIRE.
Birmingham. Town Clerk.

CITY OF PORT-OF-SPAIN.

APPOINTMENT OF A MEDICAL OFFICER OF HEALTH.

The Port-of-Spain City Council invite applications for the post of Medical Officer of Health for the City of Port-of-Spain.

The duties of the office are as set forth in the bye-laws made by the Central Board of Health and published in the Trinidad Royal Gazette of October 25th, 1917, page 1975-77.

Every applicant must be, or entitled to be, a member of the Medical Board of Trinidad and shall be the possessor of a Diploma of Public Health, Sanitary Science or State Medicine, registered or entitled to be registered in Great Britain and Ireland.

The office is a whole time one and pensionable under the provisions of the Municipal Corporations (Pensions) Ordinance, No. 29 of 1936. The salary attached to the post is £800 per annum, rising by equal annual increments of £25 to £1,000, with a travelling allowance of £75 a year.

The person appointed will be required to furnish a bond in the sum of £100 for the due performance of his duties.

Applications, stating age, qualifications and experience, should reach the undersigned at the Town Hall, Port-of-Spain, Trinidad, B.W.I., not later than July 31st, 1937.

The Town Hall, E. PRADA,
Port-of-Spain, Town Clerk.
April 29th, 1937.
Trinidad, B.W.I.

CITY OF PORTSMOUTH.

ASSISTANT MEDICAL OFFICER OF HEALTH (Male).

Applications are invited from unmarried Medical Practitioners possessing the Diploma in Public Health for the following appointment:—

Assistant Medical Officer of Health and Second Resident Medical Assistant. Salary £500-£700, rising by annual increments of £25

The gentleman appointed will be required to devote his whole time to the office, which will comprise duties in connection with Infectious Diseases, Tuberculosis, Maternity and Child Welfare, and any other duties assigned to him by the Medical Officer of Health. He will be required to reside at the Infectious Diseases Hospital.

There will be a deduction of £125 per annum in respect of the usual residential emoluments.

The position is designated as an established post under the Local Government and Other Officers' Superannuation Act, 1922, and the total salary will be subject to the statutory deduction of 5 per cent. under that Act.

Forms of application, together with conditions of appointment, may be obtained from the Medical Officer of Health, The Guildhall, Portsmouth.

Applications on the prescribed form, endorsed "Assistant Medical Officer of Health," together with copies of not more than three recent testimonials, must be delivered to the undersigned on or before Thursday, July 29th, 1937.

Canvassing, either directly or indirectly, will be deemed a disqualification.

The Guildhall, F. J. SPARKS,
Portsmouth. Town Clerk.
July 12th, 1937.

COUNTY BOROUGH OF BOLTON.

THE KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION.

Applications are invited from duly registered medical practitioners for the post of ASSISTANT RESIDENT MEDICAL OFFICER at the North Wales Sanatorium (247 beds for female pulmonary and male, female and children non-pulmonary cases), Denbigh, North Wales.

Salary £200 per annum, plus maintenance. The appointment is limited to a period of one year

Applications, stating age, qualifications, experience, etc., together with copies of three recent testimonials, should reach the undersigned not later than Thursday, August 5th, 1937.

Memorial Offices, D. A. POWELL,
Westgate Street Principal Medical Officer.
Cardiff.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE

The Secretary of State for the Colonies proposes to select within the next few months not less than five Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa or in Malaya.

QUALIFICATIONS. Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY. Initial salaries vary from £600 to £700 and rise by increments to a maximum of between £1000 and £1200.

PRIVATE PRACTICE. Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS. In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES. Free first-class passages are provided, on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.

TERMS OF APPOINTMENT. The appointments are pensionable, subject to a probationary period which varies from two to three years.

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE. Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas.

DUTIES. Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery, in public health and in medical research.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S.W. 1.

CITY OF CARLISLE.

Appointment of ASSISTANT MEDICAL OFFICER for MATERNITY and CHILD WELFARE.

Applications are invited from medical women to take charge of the Corporation Maternity Home (12 beds), Ante natal, Post natal, and Infant Clinics. The duties will also include School Medical Inspection, Supervision of Midwives, and such other Public Health duties as may from time to time be prescribed The duties of the respective offices will be carried out under the direction of the Medical Officer of Health.

Applicants must have had at least two years' experience as Maternity and Child Welfare Medical Officer, and should be in possession of the Diploma in Public Health, and preference will be given to candidates who have a special qualification in Midwifery.

The commencing salary will be at the rate of £600 per annum, rising by annual increments of £25 to a maximum of £700 per annum, and the lady appointed will be expected to commence duty at about the beginning of November.

The appointment is subject to the Local Government and Other Officers' Superannuation Act, 1922. Applications, endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, should be submitted to the Medical Officer of Health, 22, Fisher Street Carlisle, on or before August 18th, 1937.

By Order,
FREDK. G. WEBSTER,
Town Clerk.

APPOINTMENTS.—Contd.

NATIONAL SANATORIUM, BENENDEN, KENT.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Council of the National Sanatorium Association invites applications for the post of Resident Assistant Medical Officer.

The salary will be £350 per annum, rising by £25 per annum to £400, with board, residence and laundry. Annual leave will be four weeks and, generally speaking, every other Sunday will be free.

There are 147 beds at the Sanatorium and a Surgical Unit is installed.

Applications, stating age, nationality, qualifications and previous experience, together with copies of three recent testimonials, to be sent to the undersigned not later than August 3rd, 1937. Envelopes should be marked "Personal."

C. C. LAWRENCE,
Hon. Secretary.

WIMBLEDON HOSPITAL, THURSTAN RD., S.W.20. (General Hospital. 74 Beds.)

RESIDENT MEDICAL OFFICER (male, of British nationality) required for a period of six months, in the first place, from September 1st, 1937, eligible for re-election. Salary at the rate of £150 per annum, with board, residence and laundry.

Candidates must possess registered qualifications.

Applications, stating qualifications and experience, together with copies of testimonials, should be sent to the undersigned.

MRS. ASHLEY EDWARDS,
Hon. Secretary.

SWANSEA GENERAL AND EYE HOSPITAL. (336 Beds.)

Applications are invited for the undermentioned posts now vacant:

(a) *HOUSE SURGEON* for six months. Salary £150 per annum.

(b) LOCUM H.S. to E.N.T. and Ophthalmic Departments for three months. Salary £200 p.a.

Emoluments include board, residence and laundry.

Applications, stating age, qualifications, experience and nationality, to be forwarded to the Secretary-Superintendent, Swansea Hospital.

GUY'S HOSPITAL, S.E.1.

Applications are invited for the post of CHIEF CLINICAL ASSISTANT and REGISTRAR in the Department for Psychological Medicine for a period of one year in the first instance as from October 1st, 1937. The clinical Assistant appointed will be required to devote a large part of his time to psychiatric work with children. Salary £350 per annum. Whole or part-time, in any case not less than Seven Half-days per week, according to qualifications.

Applications should be lodged with the Superintendent, Guy's Hospital, on or before August 14th, 1937.

July 15th, 1937.

CENTRAL LONDON OPHTHALMIC HOSPITAL, JUDD STREET, W.C.1.

A vacancy has arisen for TWO ASSISTANT ANAESTHETISTS, and applications are invited for these positions from registered medical practitioners. Remuneration at the rate of 1 guinea per case, subject to a maximum of 2 guineas per session. Other conditions of appointment can be obtained from the Secretary at the Hospital.

NORTH ORMESBY HOSPITAL, MIDDLESBROUGH. (195 Beds)

HOUSE PHYSICIAN (male and unmarried) required at the end of August. Salary at the rate of £120 per annum, with board, residence and laundry.

Applications, stating age, qualifications, experience (if any), with copies of three recent testimonials, should be sent to the undersigned.

GEORGE WATTS,
Secretary-Superintendent.

ROYAL INFIRMARY, BLACKBURN. (244 Beds. Five Residents.)

HOUSE SURGEON (male) required. Salary £175, with board, residence, and laundry.

Applications, stating age, nationality, qualifications and experience, together with copies of recent testimonials, to be sent to the undersigned.

Royal Infirmary, Blackburn. T. DEWHURST, General Supt. and Secretary.

TAUNTON AND SOMERSET HOSPITAL, Taunton.

SENIOR R.M.O. (male) required end of July. Three Residents on staff. Applicants must have held a Resident Hospital post for at least six months. Six months' appointment, with option of applying for re-election.

Salary at rate of £200 p.a., and the retention of certain fees.

Applications, with copies of three recent testimonials, to be sent to the Secretary.

BRADFORD NEW ROYAL INFIRMARY. (345 Beds.)

RESIDENT MEDICAL OFFICER AND ASSISTANT *PATHOLOGIST* wanted (male). Salary £225. 12 months' appointment. There are 115 Medical Beds and two House Physicians. The successful applicant will be required to act as assistant to the Pathologist. Applications, stating age, qualifications and experience, and enclosing copies of three recent testimonials, should be received by the undersigned not later than July 28th.

J. J. BARRON,
Secretary-Superintendent.

THE MOUNT VERNON HOSPITAL (For Cancer.) Northwood, Middlesex.

An ASSISTANT HOUSE SURGEON will shortly be required. Candidates must be fully qualified and registered. Salary at the rate of £150 per year, with board, lodging, etc. Applications, with copies of three testimonials, to be sent to: W. J. Morton, Secretary; Offices, 32, Fitzroy Square, W.1.

THE WEIR HOSPITAL, GROVE ROAD, BALHAM, S.W.12. (30 Beds)

JUNIOR RESIDENT MEDICAL OFFICER required as soon as possible (male, unmarried). Candidates must be fully qualified and duly registered. Salary £150 per annum, with board, residence and laundry. Applications, with copies of testimonials, to be sent to the Secretary, from whom further information may be obtained.

"... I saw it in the B.M.J."

—this is what we often hear when a practitioner, having searched his memory unsuccessfully, applies to the Advertisement Department at B.M.A. House for information about some preparation or appliance which, casually noticed at the time, is now urgently required.

Our records enable us to give the required particulars and, apart from the satisfaction of helping a reader, we feel glad that yet another advertiser has reason to know that advertisements in the *British Medical Journal* "live" for more than a week.

In dealing with written enquiries, especially from overseas, we endeavour to put our correspondents into direct contact with the advertisers in whose products they are interested. By so doing time is saved and the utility of our Service is increased.

Therefore—

in case of doubt or difficulty 'phone or write—

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.
No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. SUFFOLK.—Within easy reach of sea and good towns. Old-established PRACTICE producing about £1,200 p.a. for disposal owing to ill-health. Panel of 700 patients. Nearest opposition 4 miles. Lovely Georgian house, with 2 reception and 4 bedrooms, dressing room and 2 attics. Professional accommodation with separate entrance. For sale £1,600 freehold, or might be rented for a short time. Premium £1,750 or near offer.
2. WEST COAST.—Well-established PRACTICE producing about £1,900 p.a., including Panel of 1,450 patients which gives £820 p.a. and one or two small appointments. Visits 3/6 to 12/6. Consultations 3/6, medicine extra. There is a Cottage Hospital, purchaser would get on the staff. There is stated to be scope for surgery. Suitable house on rental at £50 p.a., with rates of £26 p.a. Accommodation is ample, and consists of waiting and consulting room, dispensary with separate entrance, 2 reception, 7 bedrooms and billiard room, half-acre of garden and garage for 2 cars. Premium 1½ years' purchase.
3. WIMBLEDON.—Old-established PRACTICE for disposal. Gross income about £1,000 p.a., with Panel of 350 patients. There is also a possibility that the purchaser will obtain a hospital appointment worth about £120 p.a. House can be rented on lease or purchased.
4. LONDON, E.2.—Lock-up PRACTICE established 80 years for disposal. Income about £800-£900 p.a., with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available consisting of consulting room, dispensary, waiting room, the remainder being sub-let for £280 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £150 fittings, fixtures, drugs, etc.
5. CENTRAL LONDON.—Long-established PRACTICE for disposal owing to ill-health. Income about £2,300 p.a. Panel of over 3,100 patients. There is also an appointment producing £160 p.a., which is not included in above receipts, but which might be transferable. Suitable accommodation available.
6. CITY PRACTICE.—Lock-up, hours 10-1 and 5.30-6.30, producing about £1,000 p.a., including £200 from Panel and appointments. Suitable accommodation available.
7. BAYSWATER.—PRACTICE, established some 65 years for disposal. Gross receipts about £1,440 p.a., with 1,000 Panel patients. Suitable house on lease at £130 p.a. Premium [illegible]
8. DEVON COAST.—An 8/30ths [illegible]ER in an attractive Practice in a charmi [illegible] £5,500 including Panel producing £850 [illegible]ise with ample accommodation and nice garden [illegible] 100 p.a. *Premium 2 years' purchase. Applicant should be over 30, married, preferably with a degree and some surgical experience.*
9. SHROPSHIRE COUNTRY.—Old-established PRACTICE producing about £2,300 p.a., for disposal. Panel of 1,300 patients. Minimum fee 3/6. Good house containing professional accommodation, 3 reception and 8 bedrooms. Small garden and garage for 3 cars. Freehold £1,350. *Premium 2 years' purchase.*
10. ESSEX COAST TOWN.—A ONE-THIRD SHARE is offered to a physician in an old-established Practice producing about £7,200 p.a. Panel produces about £900 p.a. Consultations 3/6 to 7/6. Visits 5/- to 21/-. There will probably be a choice of houses. Ingoing partner should be aged 35 or over and must have a good hospital experience. He should hold the M.D. or M.R.C.P.
11. BORDERS OF NORFOLK AND SUFFOLK.—A ONE-THIRD SHARE is offered in an old-established progressive Practice, the receipts of which for last year approximate £3,300. Panel of 1,400 patients. Expenses are low. There will probably be a choice of houses. Premium 2 years purchase.
12. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be 28-40, preferably hold a degree and must have their English Fellowship. Premium 2 years' purchase.
13. NORTH LONDON.—PRACTICE producing £758 p.a., including £322 from Panel and £135 from one appointment. Fees 2/6 to 3/6. Visits 3/6 to 5/-. Suitable accommodation available, 2 consulting rooms, waiting room and dispensary with separate entrance—2 reception rooms, 7 bedrooms. Nett outgoings approximately £107 p.a. Premium £1,250.
14. HOLIDAY RESORT ON THE EAST COAST.—ASSISTANTSHIP with view to PARTNERSHIP after six months in an old-established general mixed Practice, the gross receipts of which are about £6,500. Panel of 3,000 patients and appointments produce about £550 p.a. A share to give about £1,000 p.a. will be offered to a suitable applicant who should be capable of undertaking major surgery and be accustomed to good class work.
15. LONDON, S.W.—*Old-established PRACTICE producing £1,500 p.a., with* panel of 1,266 patients for disposal. Appointment and small club bring in about £85 p.a. House available contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. *Premium £3,000.*
16. LONDON.—WEST END.—A THIRD PARTNER is required in an old-established good-class, steadily increasing Practice averaging £7,000 p.a. Share offered to produce guaranteed income of £1,000 p.a. Minimum fee 10/6. Ingoing partner should be about 30 to 33, married, hold a University degree and be used to high-class Practice.
17. NORTH-WEST COAST.—*SEASIDE TOWN.—CONSULTING* PRACTICE FOR A PHYSICIAN.—Established by vendor (who now wishes to come to London) 4 years ago. Receipts for last year stated to be £1,320. Minimum fee 2 gns. Suitable rooms available at inclusive rental of £64 p.a. Purchaser can choose his own residence and should hold the M.D. or M.R.C.P. Premium 1½ years' purchase on actual receipts for first year.
18. HAMPSHIRE.—COUNTRY PRACTICE.—Old-established PRACTICE held by vendor for past 7 years. Gross cash receipts stated to average £740 p.a. Panel of 472. Appointments worth about £130 p.a. Fees 3/6 upwards. Pleasant house containing 2 reception, 5 bedrooms, etc., Professional accommodation. Good garden and garage. Rent £55 p.a. Prem: £1,250.
19. SUSSEX.—PARTNERSHIP.—A ONE-FIFTH SHARE (producing approximately £840 p.a.) is for disposal in a particularly sound good mixed class Practice situated in beautiful country and residential district within easy reach of sea. Fees from 3/6. Suitable house with 2 sitting, 6 bedrooms, separate professional rooms. Half an acre of garden, garage for two cars. Sport of all kinds and good schools within reach. Ingoing partner should be *married*, a graduate, and aged between 30 and 35.
20. LONDON, SOUTH-EAST.—Middle-class PRACTICE held by vendor nearly 30 years, averaging over £700 p.a. Panel of 576 and one appointment worth £25 p.a. Roomy h [illegible] rage. Leasehold for sale.
21. HERTS.—Old-estal [illegible] disposal owing to retirement of Vendor. Gross cash [illegible] £1,400. Practice is a good mixed class one and the fees range from 3/6 to 15/-. Good house with ample accommodation, garden and garage on rental.
22. OUTLYING EASTERN SUBURB.—PRACTICE established over 40 years and averaging about £1,600 p.a., for disposal. Panel of about 2,000 patients. Suitable premises available at a rent of 30/- per week.
23. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £800 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¾ acre of garden, in excellent repair. Price for Practice and house, £3,100 or
24. [illegible] a young man who will un [illegible] Small compact house on re [illegible]
25. SOUTH-COAST SEAPOR [illegible] owing to Vendor's retirement. He has held it for the past 39 years. Income last year approximately £573 with a Panel of about 460 patients. Vendor previously held a public appointment producing £450 p.a., which he relinquished owing to age limit. It is considered that anyone devoting whole time to the Practice would increase the receipts. Suitable accommodation available on rental.
26. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last 12 months over £1,300 p.a. Fees 3/6 to 21/-. Nice house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, [illegible] £1,300. Sport of all kinds and schools within reach.
27. [illegible] HIN REACH OF TWO GOOD TOWNS.—Old-country PRACTICE averaging over £1,000 p.a., [illegible] over £450 a year. Low expenses. Detached house in own grounds, containing 2 sitting rooms, 5 bedrooms, etc. Rent £70 a year. Premium £1,750.
28. LONDON.—NORTH-WEST.—Recently established and steadily developing PRACTICE producing for last 12 months approximately £1,000, and increasing at the rate of about £200 p.a. Suitable house can be rented or flat obtainable. *Premium 2 years' purchase.*
29. LONDON.—SOUTH-WEST (CROYDON AREA).—Old-established good middle-class PRACTICE producing for last 12 months £1,576 p.a., including Panel of about 1,300. Suitable house with 2 reception, 5 bedrooms, etc., can [illegible] Premium 1½ years' purchase. Illness reason for sale.
30. [illegible] WITHIN 10 MILES OF HYDE PARK.—[illegible] er-class PRACTICE, steadily increasing and producing for last 12 months £760. Panel of about 560 and appointments worth £40 p.a. Good freehold house with 4 bedrooms, etc., garden, garage. Price £1,450. Premium £1,450 or near offer. Vendor retiring.
31. NORTH-EAST COAST.—Old-established PRACTICE producing about £900 p.a., but stated to be capable of considerable increase. Choice of houses. Partnership introduction given, as vendor retiring.
32. MIDLANDS.—FAVOURITE RESIDENTIAL TOWN.—Chiefly better class non-dispensing PRACTICE, producing for last 12 months over £1,600. Panel of 560 and one appointment worth £150 p.a. Fees 3/6 to 21/-. Very nice house with ample accommodation, garden and garage. Freehold for sale. Premium 2 years' purchase.
33. CENTRAL LONDON.—PRACTICE is worked as a "Lock-up" and averages about £1,000 p.a. Fees from 2/6. Suitable accommodation can be obtained. P [illegible]
34. SUSSEX.—A [illegible] NEAR SEA.—PARTNERSHIP.—A ONE-FO [illegible] (after preliminary assistantship of 6 to 12 months) in [illegible] tice having good scope. Gross cash receipts for last 12 months approximately £3,275. Panel of about 1,300. Appointments worth over £300. Choice of houses on rental for ingoing partner. Premium 2 years' purchase.
35. NORTH LONDON.—Old-established PRACTICE producing about £700 p.a., including Panel of nearly 600 patients. Suitable house, ample accommodation and good garden, garage, to rent at £100 p.a. *Premium £1,200.*
36. SUSSEX COAST TOWN.—PRACTICE established 45 years for disposal owing to retirement of Vendor. Present receipts about £600. There is stated to be scope for increase as receipts have fallen owing to Vendor's illness. Panel about 650. Large house can be rented at £150, or purchaser could probably choose own residence.
37. LONDON.—SOUTH-EAST.—Old-established PRACTICE producing about £1,830 p.a., including select panel of 500. Fees from 3/6. Suitable house *available with 2 recep., 5 bedrooms, etc.* Freehold for sale. Prem. 2 years' pur.
38. RIVERSIDE TOWN.—Well-established middle-class PRACTICE producing for last 12 months approximately £940. Selected panel of 400 to 450 pat [illegible] Visits from 5/-. Very nice house in good repair, with ample accommodation. Garden. Garage. Price for freehold £2,000. Premium £1,250.
39. SOUTH CORNWALL.—FAVOURITE COAST TOWN.—Well-established PRACTICE averaging over £1,100 p.a., including selected panel of about 350. Fees from 5/-. Good freehold house for sale or smaller house available. Premium £2,000. Vendor retiring.

WANTED TO PURCHASE.—PRACTICE OR PARTNERSHIP producing £500 p.a. upwards, and situated within 2 miles of Highgate.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

Published by the Proprietors, the British Medical Association, Tavistock Square, London, W.C.1, and printed by Eyre and Spottiswoode Limited, East Harding St., Fleet St., London, E.C.4. Printed in Great Britain. Entered as Second Class at New York, U.S.A., Post Office.

. . . . . it may happen to-day

The course of events cannot be foretold. Everyday risks in the home, in the car or whilst walking in the street, may at any moment bring realization of the need for adequate insurance against unavoidable dangers. Accidents apart, protection from disability caused by ill-health should be provided. In this way only can one's self and dependents be safeguarded against misfortune.

What do I gain by Insurance?

. . . . . it may not happen at all

And if none of these things should happen, but a life's hard work be rewarded by retirement at a reasonable age, wise insurance will still confer real advantages.

Peace of mind, knowing that all risks are provided against, cannot fail to influence for good the health of a busy man.

The insurance taken out in earlier years will bring a regular pension or a lump payment which may be extremely useful in compensating for the fall in annual income resulting from the cessation of active work.

ALUZYME

NON-AUTOLYSED YEAST

Professional samples, descriptive matter and prices on request

ALUZYME PRODUCTS
PARK ROYAL ROAD, LONDON, N.W.10

THE GUARANTEES OF EFFICACY

Aluzyme is plain Brewers' Yeast, stabilised by dehydration at a low temperature. This leaves the cells intact; Aluzyme contains 95% of vital cells and therefore provides all the essential constituents of yeast in the fully active state of living substance. Officially certified Vitamin potencies: B_1: 1140 Internat. Units per ounce. B_2 Complex: Maximum for Dried Yeast. Sulphur content, 0.47%; Nuclein, 0.4%. Glutathione reaction, brilliant magenta. Its therapeutic value in *B* avitaminosis, furunculosis, and the *Anaemias* is apparent from these particulars.

THE "DOCTORS' SHIRT" *which has detachable sleeves!*

Here is a most useful shirt which for many years we have supplied to the medica profession. With detachable sleeves just above the elbow, it fastens with four smal buttons which are adjusted with a minimum of troub'e. The "Doctors' Shirt" possesses also these additional points o interest.

1. It keeps the cuffs smooth instead of being creased up by the process of rolling

2. There is no fear of them coming down at an inopportune moment.

3. There is no muster of material about the biceps to interfere with the action of the arm

The "Doctors' Shirt" is made in white poplin 10/6, Collars 1/3 extra. Extra hali sleeves sold separately. Also other fabrics striped or plain. For prices, patterns, and self-measurement forms send to Dept. B.M.J.

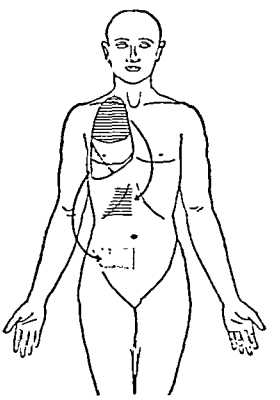
THE "BRITISH MEDICAL JOURNAL" and "THE LANCET" commend

Major's Physical Diagnosis

"BRITISH MEDICAL JOURNAL"

"The classical methods of physical diagnosis as an important factor in the clinical examination of the patient have during recent years been subject to the competition of instrumental and laboratory developments, and at times enthusiasts for the new services have been inclined to disparage the older order. It is a useful enterprise to recall attention to the patient as the central factor in the clinical problem and to show that bedside examination continues to claim a large share of the physician's attention and judgement. In his 'Physical Diagnosis' Professor Ralph H. Major undertakes this enterprise, and his teaching is both pleasantly and effectively presented."



"Altogether the book is justified as an assertion of the value of methods which need training and patience to make them effective and which are perhaps apt in an age of hurry to suffer by comparison with more dramatic proposals. The ancient ways are fortunate in having an advocate so informed and so persuasive as Professor Major."

"THE LANCET"

"This valuable text-book on physical diagnosis embodies fifteen years' experience in teaching by an enthusiast for clinical medicine. Though the personal element is essential for teaching at the bedside it can be tiresome and pedantic in print, but Professor Major is not guilty in this way; his tone is not didactic and he makes use of all the recognised authorities and recent work with frequent quotations and extensive lists of references. . . . The many excellent photographs, the helpful diagrams, and, above all, the impulse of Dr. Major's enthusiasm may transmit to the student the thrill which will send him to the bedside, there to look, listen, and feel for himself."

Octavo of 457 pages, with 427 illustrations. By RALPH H. MAJOR, M.D., Professor of Medicine in the University of Kansas. Cloth. 21s. net. Published February 1937.

From the CHAPTER on PAIN

Projection of pain to abdomen in pneumonia.

Read, too, what "THE LANCET" says of

Mason's Pre-operative and Post-operative Treatment

"This is an excellent book, containing practical wisdom with sound theory, and giving adequate consideration to the application of biochemistry to therapeutics. In its preparation, Dr. Mason has had the assistance of twelve colleagues who have contributed chapters on subjects to which they have devoted special attention, and a uniformly high standard in many special branches is thus achieved. The references to the literature are up to date and well chosen. The most notable feature is the emphasis laid upon the adjustment of water-balance, and the control of the sugar and salt content as well as the reaction of the blood before and after operation. These matters are of such importance for the proper function of every tissue in the body, and are so often upset both by the patient's disease and by the surgical procedures adopted for its relief, that they must form the basis of rational treatment.

. . . a book which should be studied by everyone who undertakes the care of surgical cases."

By ROBERT L. MASON, A.B., M.D., F.A.C.S., Assistant in Surgery at the Massachusetts General Hospital. Octavo of 495 pages. Illustrated. Cloth, 25s. net. Published March 1937.

SALTAIR SURGICAL SERVICE

THIS

IS A PRACTICAL SAFEGUARD TO PRACTITIONERS WHO ORDER

SALTAIR SURGICAL APPLIANCES

For many years now the above Guarantee has been featured in all SALT'S advertisements. It can be taken literally, for it means exactly what it says. Though the return of a SALTAIR Appliance is a very rare occurrence (due to careful observance of individual measurements and data) we are nevertheless sure that Practitioners appreciate such a definite Guarantee, which completely removes any possibility of financial loss for the doctor who orders a SALTAIR Appliance for his patient. Catalogues of appliances sent post free on request.

London Consulting Rooms
"OAKLEY HOUSE,"
14-18, Bloomsbury Street, W.C. 1
Female fitters in attendance Monday to Friday.
Orthopaedic Mechanician Wednesdays only.
By Appointment.

'VARIBAN' ELASTIC PLASTER BANDAGE

"VARIBAN" BANDAGE constitutes a marked advance on the older methods of treating chronic ulceration of the leg. It is made from a specially woven selvedge material possessing highly elastic properties, and is impregnated with an antiseptic zinc oxide paste.

"VARIBAN" is self-adhesive and combines the principles of firm, equable pressure and support to the swollen leg, with the benefit of an occlusive dressing under which the ulcer is protected and is stimulated to healthy repair.

In promoting proper circulation, "VARIBAN" steadily reduces oedema. It provides protection to the granulations of the healing ulcer. In the majority of cases it is found that pain is either eliminated or greatly relieved from the first application. The necessity for ointments, lotions, etc., is obviated, while "VARIBAN" provides an ambulatory treatment which allows of full activity of the limbs with better results than those following rest in bed alone.

DESOUTTER

CASE RECORDS

Case No. 2159/1472. 1935

Miss A., a hospital patient, aged 25 years, was sent to us in April, 1935. She had had both legs amputated below the knee eight years previously as a result of septicemia following an accident. Owing to general ill-health and lack of funds she had not been fitted with limbs but for seven years had managed to get about the house on her knees, causing deep-seated callouses to develop. See Figure 1. Apart from these callouses she had a good 7 in. left stump which was easily fitted with the normal below-knee limb. The right stump, on the other hand, was extremely short, only 1½ in. of tibia being left, and it appeared on first sight that the patient would have to be fitted with a kneeling appliance. However, on examination, it was found that as the leg had been amputated immediately below the tibio-fibula joint there was an exceptionally large bone surface which made it possible to use the end of the stump as a weight bearing point, and with the remanent of calf muscle being used to obtain a retaining grip, a normal below-knee type limb was fitted with only a slightly longer thigh corset to give additional lateral support. Although this is without doubt the shortest stump to which it is possible to fit a below-knee limb the patient has good control over both limbs and walks well with natural knee actions.

Maderite COME BACK ALIVE...

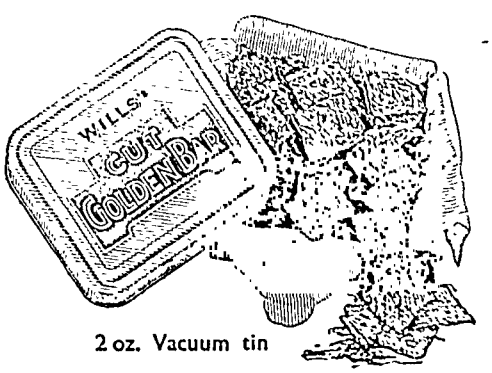
from the Autoclave

Time and time again they do it. Even after enough sterilization to put an end to many brands of rubber gloves, *Maderite* brown milled Surgeons' Gloves come back alive and elastic.

While you are getting this extra wear, you have the fine operating features of greater thinness and tactility. Your touch is delicate and sensitive—yet the friction is there for a firm grip. Fingers are free—never cramped. In short, you virtually forget you have gloves on.

Test these remarkable gloves yourself. Try a pair. Note the roughened surface which gives you the friction to grasp and manipulate instruments firmly. Test their strength at the wrist and the uniformity of the fingers.

TRADE MARK SR REGISTERED



Use *Maderite* Gloves for their properties of tactility and mobility and for economy's sake.

Made by the manufacturers of Seamless Standard Latex Surgeons' Gloves, the famous tissue thin, quality white gloves.

TWENTY-FIVE per cent. of the flour from which the HOVIS loaf is produced is wheat germ

Science advocates the use of germ-bread as a factor in promoting nutrition. That is why HOVIS figures so prominently upon the dietary when the question of food value must be studied. In white bread, the wheat-germ is practically non-existent. This vitalising source of protein, fats and phosphates abounds in HOVIS. In fact, twenty-five per cent of the flour from which the HOVIS loaf is produced, is WHEAT-GERM. Apart from its low starch-content, HOVIS is practically free from bran and indigestible cellulose. This factor makes HOVIS supreme for easy digestibility and assimilation.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anæmia and indeed in all the simple anæmias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

'PEPSENCIA'

Is radically different from the ordinary fluid "pepsin" preparations because it contains the entire soluble constituents, organic and inorganic, of the stomach glands, all the various complex potent catalytic constituents. It is not made by dissolving "pepsin" in a vehicle; it is an entire gastric juice extract.

To prescribe 'Pepsencia' is to give the patient the benefit of a standardised product of long maintained reputation and efficacy, of established value in medical practice as a digestant, a vehicle, and as an aid to other treatment.

Supplied in four sizes: 4-oz., 8-oz., 16-oz., and W. Qts.

Originated and manufactured by
Fairchild Bros. & Foster (Inc. N.Y.),
NEW YORK and 65, Holborn Viaduct, LONDON, E.C.1.

Agents:
Burroughs Wellcome & Co.,
LONDON, SYDNEY, and CAPETOWN.

MANDELIX

(Elixir of Ammonium Mandelate B.D.H.)

In Urinary Tract Infections

Mandelix therapy possesses the following advantages:

1. The elixir is administered orally, and supplementary administration of ammonium chloride is unnecessary.
2. The flavour of Mandelix is acceptable, and the treatment has the willing co-operation of the patient.
3. Sterile urine is produced usually within a week, even in chronic infections.

The Constipation of Childhood

THE treatment of constipation in infancy and childhood calls for special care. The young and often delicate organism cannot with impunity be subjected to the drastic effects of many depuratives. Often, too, there is an associated defective assimilation which also requires the consideration of the physician.

"Cristolax" admirably meets the need for a gentle corrective. It is perfectly harmless and free from the possibility of habit formation. This efficient lubricant is composed of "Wander" Dry Malt Extract with which is incorporated 50 per cent. of pure medicinal liquid paraffin of correct viscosity.

On account of its pleasant flavour, easy administration, and its gentle yet efficient laxative action, "Cristolax" is the agent of choice for infants and children. Its soothing effect on inflamed mucosa permits its use in infantile diarrhoeas, colitis, and other irritated conditions of the bowel.

Design from Greek Vase.

A Warrior running, directing his spear against a Pursuer, who is not shown.

Improved ointments

By treating lanolin with milk albumin and fluoro-silica colloid, an emulsion is obtainable which, by the improved physical structure imparted to the wool fat, possesses an exceptional affinity for the skin, and, therefore, excellent penetrative action.

Fissan Brand Basic Ointment combines the properties of a superior vehicle for medicaments with that of a therapeutic agent possessing marked antipruritic qualities.

Fissan Brand Paste is an improved compound zinc ointment prepared with the Fissan base.

Fissan Brand Anal Ointment and Suppositories are effective applications for the relief of anal pruritus. They embody the soothing and healing properties of milk albumin, together with further medicaments, in a base that is rapidly absorbed by the mucous membrane.

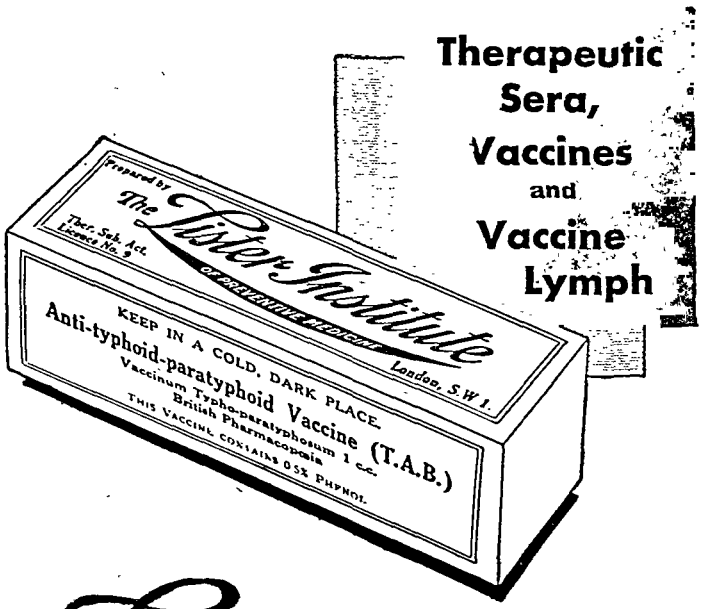
THE THERAPEUTIC VALUE OF THE BANANA

1. The Enzymes The banana is comparatively rich in enzymes, amylase, sucrase, a protease and a lipase being present.

Of these, perhaps the protease is of the greatest value to the convalescent, owing to its faculty of splitting up protein into the simpler soluble nitrogenous bodies (amino-acids) necessary to tissue-building.



Protease is also notable for breaking down the casein of milk, forming tryptophane, the most important amino-acid of them all.

It is for this reason that so many medical men are prescribing a mash of milk and bananas for convalescents and young children, especially in cases of coeliac disease.

N.B. In the fully ripe banana the starch content is reduced to about 3 per cent, having been changed into soluble sugars. A banana is ripe when all green has disappeared from the skin and brown spots have formed upon the yellow surface.

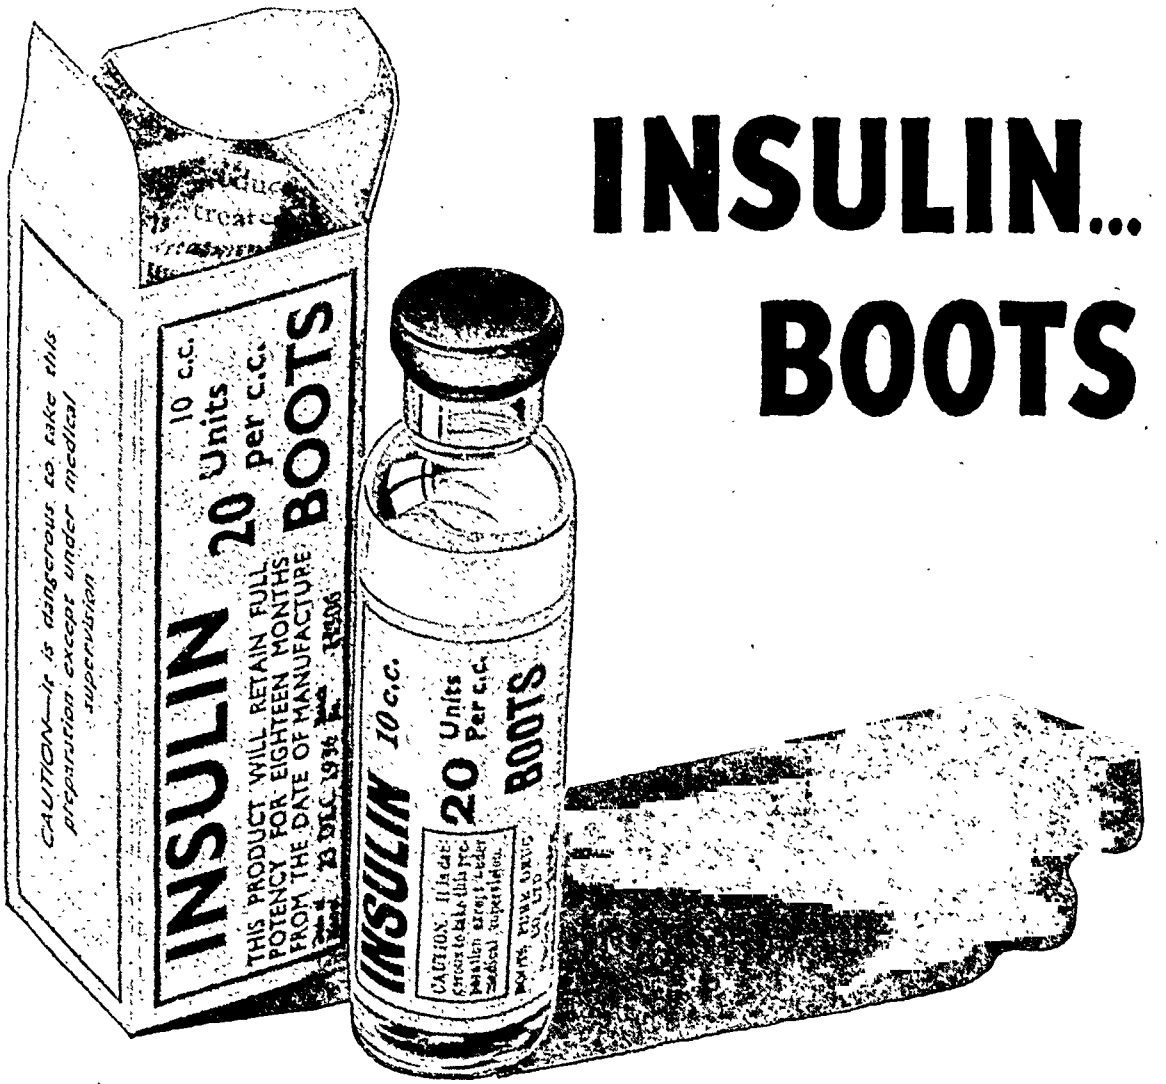
Anti-typhoid-paratyphoid Vaccine (T.A.B.)



It is nowadays customary to combine in one vaccine the protective agents against typhoid and paratyphoid A and B fevers, which are all liable to occur in similar circumstances. T.A.B. vaccine contains 1,000 million *B. typhosus* and 500 million each of *B. para-typhosus* A and B per cubic centimetre. Inoculation with this vaccine is strongly recommended for nursing staffs in fever hospitals and persons proceeding to infected areas anywhere (*e.g.*, on holidays in many Continental countries), or to the tropics. Double inoculation (½ c.c. followed by 1 c.c. 7 to 10 days later) produces an immunity regarded as lasting about 12 months, at the end of which a further dose of 1 c.c. is advisable to maintain the immunity.

SUPREME QUALITY IS BURROUGHS WELLCOME QUALITY

The "Sunic Junior" Outfit is ideal for Fracture Clinics, Small Hospitals, Welfare Departments and Private Practice.
(*Photo: Medical Patents*)

When X-ray examination is Urgent—

When delay may prejudice the patient's chances of recovery, the possession of a "Sunic Junior" X-ray Outfit is invaluable. Without any elaborate preparation, a radiograph or screen examination can be made immediately—with complete safety and with the knowledge that the results will be entirely satisfactory.

The "Sunic Junior" Outfit is shockproof and rayproof, free from complicated controls, yet remarkably versatile. It occupies little space and will operate for years without trouble of any kind.

We will gladly arrange to demonstrate this popular British-made equipment at any address in Great Britain without obligation.

REMOVAL OF RIGHT OR LEFT FRONTAL LOBES IN MAN*

BY

GEOFFREY JEFFERSON, M.S., F.R.C.S.

Neurological-Surgeon, Manchester Royal Infirmary; Surgeon, National Hospital, Queen Square, London

In the early days of the neurological renaissance that followed the discovery of localized function in the cerebral hemispheres the frontal lobes seemed to select themselves as the seats of the intelligence by a process of exclusion. Once the motor, the sensory, the visual, the auditory, and the olfactory areas had been roughed out upon the cortex and the tracts coming to and from them plotted with gradually increasing certainty (a task to this day uncompleted), it was but natural that speculation should be busy with those large areas still remaining which were unresponsive to stimulation and often, but not always, curiously "silent" to destructive or disease processes in man.

Those of us who "teethed" in study twenty-five years ago did so on the cortical maps of Flechsig, Elliot Smith, Campbell, Brodmann, and the Vogts, and learned that the grey matter consisted of numerous areas with different developmental histories and with different histological structures. This was true not only of the projection areas but also of the various association areas, and it was demonstrable that the frontal lobes, like other parts, had not one single homogeneous structure, but were subdivisible again into several cantonments, the most posterior of which formed the motor cortex. The work of Ferrier, of Horsley, and of Sherrington in particular, allotted definite functions to the different parts of that latter area, though our knowledge even of the apparently simple motor cortex is not yet complete (see, for example, the revival of interest excited by J. F. Fulton (1932), then by F. M. R. Walshe (1935), and more recently by D. E. Denny-Brown).

The Problem of Frontal Lobe Function

Since some areas of the whole patterned cortex were known from the early days of the newer knowledge to possess specific functions—functions evidently related to structure—it seemed to be only a question of time, and of opportunity of the right kind, before these would be allotted in a similar manner to the so far silent remainder. The deduction that distinctive histological structure portended distinctive and discoverable activities was, and still is, an irresistible one. But it remains to make these areas reveal their local secrets. We have become so deeply impressed with the importance of local areas, especially the motor, that we are almost certain to assume that function is equally local in the silent localities and that a small lesion of a frontal lobe will be likely to produce an equivalent paralysis, in this case of the intellect or in emotional control. But there is in such a conception something of the absurdity that we recognize so clearly in the earliest work on the localisms of cerebral function, that of the phrenologists Gall and Spurzheim. Clinical observation has not succeeded in solving the problem of frontal lobe function, for whilst recognizable alterations of the expected kind are quite commonly present they are in some cases lacking. Moreover, paradoxical cases are met with in which there is intellectual deficit and a lesion is discovered at operation or necropsy in quite another part of the brain. The most useful evidence of the functions of the frontal lobes (since electrical stimulation has so far failed to yield anything informative) and the solution to some of these problems ought to come from cases in which one or both were removed in man. I have no personal knowledge of a bilateral removal, but reference will be made later to the only two cases which have been carefully studied and published.

Eight Case Histories

It is the purpose of this paper to present some examples of unilateral lobectomies, both left and right, and to set down as fairly as possible what the effects have been. There are eight cases in which one or the other frontal lobe was successfully removed. Two of these patients died subsequently, one of an intercurrent disease. Six are still alive, and, since three happen to be left-lobe removals and three right, they make an interesting group for comparison. The cases are of necessity described very briefly, and a great deal of negative evidence which might be demanded for scientific accuracy has been suppressed. It is hoped that at a later date some of these cases may be made the subject of closer psychological analysis by more competent hands than mine.

It is not my intention to enter into a long discussion of the symptomatology of frontal lobe tumours, for this is well enough illustrated by the cases themselves. It will be observed that the syndrome may vary with the type of lesion and a recognizable deficit be absent, so that fits and failing vision may be the only features to call attention to disease. Something will have to be said later about the reasons for the differences—why one case should show signs and others none; and especially we shall have to discuss the results of the operations.

Case 1

A female aged 22 was referred by the late Dr. Core to the Manchester Royal Infirmary, February 19, 1932. When seen in consultation the following note was made:

The patient sits propped up in bed and seems very cheerful and comfortable. She was pleasant and co-operative, but often slow in answering, though by no means always. She did not realize the seriousness of her state, and said she was very well. She declared that she had no headache at the time nor had she suffered from it. (This was untrue—she had suffered severely from headache and had had some bad crises; a few

* Based on a paper read before a joint meeting of Rochdale, Heywood, and Oldham Divisions of the British Medical Association on April 9, 1937.

days previously she had been really very ill with it.) Questioned on the onset of her illness she was very vague, but she knew how long she had been in the hospital, her full name, and where she lived. Often a striking point was the hesitation before she answered, as if she had not heard the question at all. She was not deaf. When the question was repeated she answered, but maybe after a brief pause. She spoke rapidiy enough, and never made a mistake in the arrangement of her words or use of nouns or verbs. Another obtrusive feature was her lack of volition. She spoke without vivacity with very few movements, and in a long conversation scarcely changed her posture once. She volunteered no remarks. She was completely apathetic about food, never asked for it or showed any interest when meal-times came round. Her ideation was evidently limited, for she was unable, as it were, to weave any patterns on ideas suggested to her. She thought that she had only been ill since her admission to hospital, but in this she was inconsistent, for soon she dated her illness as far back as November. (The actual date of onset, so her mother informed me, was the previous spring, and she had had to give up work because of headache and failing vision in October. She had been treated for indigestion because of vomiting, and had seen an eye specialist, who gave her glasses.) Her headache was frontal and not lateralized. She had had several attacks of twitching in her left hand. Two very brief attacks while she was unconscious had been observed in hospital, both occurring when her headache was fierce. It was thought that her right arm was drawn up close to the body, unconvulsed, in these attacks, and that the left side was quite silent. She was incontinent the rest of the day after these attacks, although quite conscious. It was interesting to observe her lack of interest in her incontinence. She forgot about it between-whiles, and when it happened passed it off as none of her business, or another time said that she voided before she realized what was happening.

Clinical examination revealed high-grade choked disks, relative anosmia in the right nostril, slight hypertonia on the left side, but no loss of motor power, no grasp reflex, left abdominals easily exhausted, equivocal left plantar reflex, flexor right. There were no radiographic abnormalities. The diagnosis was: right frontal tumour, probably a glioma.

Operation (*March 2, 1932*).—A right frontal osteoplastic flap was turned down. On opening the dura the cortex was pale and the gyri flattened. A high posterior puncture was made to tap the anterior horn of the right lateral ventricle but struck a gliomatous cyst at a depth of three centimetres. The cannula was at once withdrawn and the cortex incised down to the cyst wall after underrunning the cortical vessels with silk. The cyst was deep, and near the midline there was an obvious neoplastic lining. It was thought that the best way of dealing with it would be to excise the frontal lobe with the tumour inside it. The slightness of the pyramidal signs denoted that the posterior end of the tumour lay definitely in front of the motor cortex. The frontal lobe was thereupon excised, but the line of section ran into gliomatous tissue, and it was seen that the tumour was too extensive for complete extirpation. The invaded area was very thoroughly diathermized. The line of section ran obliquely upwards and backwards from the lesser wing of the sphenoid, but a thin shell of the frontal lobe was left behind mesially and inferiorly.

The effects of this excision on the patient were remarkable. It might have been thought, since she was already slow and apathetic through harbouring a tumour in the frontal lobe, that frontal lobectomy would have made her worse by removing still more normal and functioning brain tissue. Exactly the opposite happened. Next day she was extremely well, and whereas she had never before spoken unless addressed, and not always then, she now spoke readily and at first rather excitedly but sensibly. She was worried about her personal appearance, for her right eye was closed by a temporary oedema. The incontinence of both urine and faeces which had been so troublesome a feature stopped within twenty-four hours of the operation. There was no trace of contralateral palsy. She professed herself at the end of a week to be entirely well; she was able to give details as to where she worked and when she stopped work, as well as points in her earlier clinical history upon which she had before been very hazy. She moved about more readily in bed, and seemed to have an interest in life that had been lacking. She took her food well, and behaved very much as did the other patients in the ward.

The histological diagnosis in this case was astrocytoma with areas of malignant change. Probably the tumour should be regarded as a glioblastoma multiforme.

The patient was put on deep *x*-ray therapy and returned home. She remained to all intents and purposes normal for eight months, when she had a return of her previous symptoms and died fourteen months after her operation. As far as the frontal lobe removal was concerned the experience was encouraging, for it demonstrated that the mental disturbance associated with a frontal tumour could be relieved by lobectomy and not made worse, a very important point and one of which little was then known. It remained to apply the operation to a patient with a tumour not so far advanced as to transgress the limits of possible extirpation. No further opportunity arose until April, 1935.

Case 2

The next case can be very briefly reported because the patient died of an intercurrent disease seven weeks after operation. The case is useful only as a piece of evidence that the frontal lobectomy did not, so far as could be seen, seriously affect his mentality.

C. B., aged 44, was transferred on March 25, 1935, to the Neuro-Surgical Service from the medical wards of the Manchester Royal Infirmary by Dr. Fergus Ferguson with the diagnosis of right frontal tumour, probably astrocytoma. He had been admitted on account of his fourth series of severe convulsions, the first having been in 1928. In each of these series his fits had amounted to status epilepticus, but after a few days he had recovered completely and returned to his duties as a clerk almost at once. After the last series he had had much more headache, and had seemed rather slow in speaking and more drowsy than he should have been. Bilateral papilloedema was discovered, and the radiographs showed a calcifying tumour in the right frontal lobe, well forward. He had performed his duties perfectly well until the last outbreak of epileptic seizures that brought him into hospital.

On April 2, 1935, the voluminous right frontal lobe containing the tumour was removed, leaving the anterior fossa empty, the olfactory nerve being clearly seen in its floor; the falx was left bare on its anterior seven centimetres. The pericallosal vessels were exposed running round the genu of the corpus callosum. The mesial surface of the opposite frontal lobe was visible. The large cavity was filled with Ringer's solution and the flap replaced. The duration of the operation was five and a quarter hours. Next day the patient was relatively well and said he wanted to smoke. On the fourth postoperative day a conversation with him was taken down verbatim in shorthand. It was designed to test his memory, and disclosed no defects. He talked about his work, his children, and his home without difficulty He lay rather quietly and did not move about the bed much, but he spoke rather loudly, and his manner was a little aggressive, though perfectly friendly and good-humoured. He complained of coldness of the feet, but made little effort to stir his limbs, though he could do so freely when requested. This lack of initiative was perhaps significant. On the other hand, he said that he would like to get up and sit in a chair as a change. His mouth and teeth, which had been very dirty, remained so, owing to keeping his tongue and lips very still. He was not incontinent. He smoked incessantly when allowed, but gradually he became more normal and quiet in manner, and was discharged to the convalescent hospital a month after operation. Two weeks later he contracted facial erysipelas and died of pneumonia in Monsall Fever Hospital.

At necropsy the operation wound was seen to be perfectly healed. There was no intracranial infection. The truncated anterior end of the right hemisphere was covered by dura firmly adherent to the cut surface. Histological diagnosis: astrocytoma.

This case is robbed of its full value by the short survival of the patient. During the first days after his operation his state was not entirely normal, although he was in possession of his faculties so far as they could be tested. After that he steadily improved, but unfortunately a really detailed inquiry into his later condition was postponed, and then was prevented by his unexpected death. I should have been left uncertain about frontal lobe function if this had been the only case in my experience, but Case 1 had already been observed, and those that follow leave no doubt at all. In the remaining six cases the patients are all alive still, and in three at least the removal of the lesion has been so complete that their continued survival is certain. The three right lobectomies will be taken first, then the three left, though that is not their chronological order. Since the technical steps involved in these operations are very similar in all cases they will be but briefly referred to.

Case 3

Right frontal oligodendroglioma. Removal of right frontal lobe. Recovery.

Mrs. L., aged 35, was referred by Dr. Carleton of Bristol on September 13, 1935. Twelve months previously she had commenced with intermittent attacks of headache and vomiting which were thought at first to be "bilious." In addition there were attacks of dizziness, during one of which she fell and hurt herself, and had to remain in bed for a week. Whilst recumbent she had another bad vertiginous episode. She vomited severely in all of these attacks. For the last few months she was no longer sick, but had headaches of great severity at intervals of about one month, commencing usually about 2 a.m. and lasting for one or two days. The pain was all over the head, but chiefly on the right side and at the back, with some stiffness of the neck. During these acute spasms of pain it seemed to relieve her if she could hold someone's hands and dig her nails into their palms; whilst doing this she stood with bent head, her face flushed, perspiring visibly, and breathing rapidly. On this account the case was for long regarded as one of migraine with a hysterical overlay. Latterly she had become touchy and irritable. Her memory was said to be bad, but very few useful illustrations of this were forthcoming. If she went to the cinema she could not remember when she got home what the film had been about (this struck her friends as remarkable). Vaguely, also, she felt that she could not concentrate. She consulted Dr. Carleton, who found bilateral papilloedema and an extensor left plantar response. She was referred to me. Acuity was normal and the fields were full; no other signs were elicited other than those recorded by Dr. Carleton: no anosmia, no hypertonus, no grasp reflexes. Stereoscopic radiographs by Dr. Twining brought to light scattered calcification low down in the right frontal lobe. Diagnosis: right frontal glioma, probably oligodendroglioma.

Her hypertensive attacks were peculiar and suggested a third ventricle tumour until the radiographs cleared the issue. She was bright and quite alert, except during or after her violent attacks of pain, but her husband was aware of an indefinable change in her. She was admitted to a nursing home, and on September 29, 1935, the right frontal lobe was removed. The line of section passed through the frontal horn of the lateral ventricle. The mesial surface of the left frontal lobe seemed to be superficially invaded by the tumour and the posterior line of section was not above suspicion. After a blood transfusion the wound was closed. She made an uninterrupted recovery. Forty-eight hours after the operation she was reading the newspaper and carried on a normal conversation with me. Her conversations were recorded verbatim, and they showed no defect whatever. She has been having deep x-ray therapy since, and has been seen from time to time.

Re-examined in March, 1937, eighteen months after operation, she says she is as well as ever in her life, and her husband privately agrees with this. Her memory, concentration, and demeanour are all normal. She does a great deal of housework, cooking and so forth, reads, sews, and listens to the wireless. All the frontal lobe signs which she had until her frontal lobe was removed have gone. I have interviewed the husband as well as the patient more than once, and have tried to get him to allow that something was amiss, but he will never admit to anything at all. She always had been a friendly sort of person, and he is sure she is not more so now; she was naturally good-tempered, but apt to lose her temper and regain it very quickly. These traits have not been modified. Histological diagnosis: oligodendroglioma.

Case 4

Mrs. E., aged 45, was admitted to the National Hospital, Queen Square, under Dr. Purdon Martin, on February 14, 1936.

Three years previously she had consulted an optician because her eyesight was failing. Four years ago she had begun to suffer from generalized headache, which sometimes wakened her in the night. Sudden jarring or sneezing greatly aggravated the headache, which was intermittent and, though not becoming more severe, was becoming more frequent. Eight months previously she discovered that her right eye was blind. Whilst in hospital in Southampton, a month before admission to the National Hospital, she had a convulsive seizure in the night about which she knew nothing. On examination there was primary atrophy of the right optic nerve, and two dioptres swelling of the left. Apart from diminution of the sense of smell in the right nostril there were no other neurological signs. Radiographs showed a localized hyperostosis over the right optic canal—an important point, the significance of which has been commented upon elsewhere (Jefferson, 1936). There were no mental and character changes, and she was perfectly orientated in time and place. She was operated upon by me on March 12, 1936. A right frontal osteoplastic flap was turned down and a large basal meningioma removed. The right frontal lobe had to be excised in order to get proper access. The operation was arduous, the duration being five and a half hours. Apart from pyrexia during the first week convalescence was smooth. Owing to this patient living at a distance contact has had to be maintained by letter. In March, 1936, she stated that she was better than she had been for years and had no disability, mental or physical, whatever, except for the blindness of her right eye. She works as a housekeeper.

The next case is too recent for any final assessment, but since it illustrates well the disappearance or at least amelioration of frontal lobe signs following removal of the lobe it is worthy of inclusion.

Case 5

Mrs. H., aged 49, was admitted to the National Hospital, Queen Square, under Dr. C. P. Symonds, on January 7, 1937. Her history as given by herself was unreliable and needed correction by her husband on many points.

Two or three years ago she began to suffer from occasional headaches and from peculiar fainting attacks in which she did not quite lose consciousness (minor epilepsy). Four months previously her husband returned home and found her in a peculiar dazed state. She was confused and unable to give any account of what had happened. She had vomited. She recovered in a few hours, and then had no recollection whatever of the incident. From that time her headache increased in severity, and was at times, especially during the night, almost unbearable for half an hour. She became very confused during the worst headaches. She tried to do her housework, but was incapable of either initiating or completing the simplest

task. She began to show definite forgetfulness and mental deterioration. She was well aware of the undependability of her memory, and would ask her friends not to tell her things, as she would be certain to forget them. On admission, questioned about an abdominal scar, she said she had had her appendix removed a good many years before. She did not know when or where. Pressed for an explanation, she said that she had not had an operation after all. She was a well-nourished healthy woman with a mild dementia. She could not remember the name of the present King. She resented physical examination in a playful, shallow way. There was bilatertal papilloedema and no pyramidal signs. Radiographs disclosed a linear calcification in the right frontal lobe. Diagnosis: right frontal astrocytoma.

On February 11, 1937, the right frontal lobe was removed, the line of section running upwards and backwards from the lesser wing of the sphenoid and cutting through the lateral ventricle. There was no great alteration in cortical pattern, but puncture disclosed a tumour at a depth of three centimetres. On taking several readings it was found to come closest to the lower surface. There was no sign of tumour breaking through the mesial surface, as is so common in apparently unilateral frontal tumours, so a complete excision was carried out. There was a suspicious area to the inner side of the ventricle, seen after it had been cut across. The duration of the operation was two and a quarter hours. A month later this patient was greatly improved. Prior to the operation she was an aimless sort of being. The ward sister reported that she would sit for hours with a plate of food and not finish it, or if she went to the bath would have sat in it all day if she had not been got out (suggesting Flourens's decerebrate chickens). After removal of her frontal lobe she gave a different impression, seeming to have a purpose—to know what to do and to get on with it. In conversation she seemed nearly normal, and lost her facetious manner. She was never incontinent after her operation, though previously she had occasionally been so. There was a slight left-sided facial weakness for a time afterwards, but no weakness in the arm or leg, and there was no grasp weakness.

I am unwilling to accept this patient as entirely free from signs at the time of writing. Her powers of memory are not yet all they should be, but her alteration for the better is striking. She was up and about the ward at the end of two weeks. Her husband has written to say that she is normal mentally, and in reply to a detailed questionary he reports her, on all points, as having no abnormalities. But in June she had a convulsion and lost ground afterwards. Her future is uncertain, not because of the lobectomy but because of the likelihood of recurrence.

Removal of Left Frontal Lobe

The remaining three cases had the left frontal lobe removed; they also are presented in chronological order.

Case 6

Mrs. W., aged 32, was admitted to the National Hospital, under Dr. C. P. Symonds, complaining of blindness in the left eye, failing vision in the right, anosmia, severe headache, and "fainting turns."

The diagnosis of left frontal basal meningioma was made and, since she did not desire to run the risks of tumour removal at that time, a right-sided subtemporal decompression was performed. She was readmitted on March 19, 1936, because her fainting attacks were becoming more frequent and for a month past her headaches had returned. She also thought the sight of the right eye was declining again. The decompression had meanwhile varied, sometimes tight, sometimes slack, but always bulging to some extent. Neurological signs were as before: left optic atrophy, blind left eye; right papilloedema, field normal save for enlargement of the blind spot. She had anosmia, and protein increased in the cerebro-spinal fluid to 200 mg. On April 30, 1936, a left frontal osteoplastic flap was turned down and a small meningioma was found growing from the falx. The superior longitudinal sinus and a section of the falx were removed, whereupon a second, much larger, meningioma was seen arising from the olfactory groove. The left frontal lobe was resected to give access to this tumour, which was removed in its entirety and its point of origin heavily endothermized. The duration of operation was five hours and forty minutes. One blood transfusion was given after four hours.

One hour after the close of the operation the patient spoke to the operator and said that she felt all right but was afraid of the ordeal which she thought she still had to undergo. Her convalescence was uneventful; at no time did she show any evidences of mental disturbance. She has been re-examined at intervals during the past eleven months, and was shown at the clinical meeting of the Neurological Section of the Royal Society of Medicine in February, 1937.

She does all the housework, shopping, and mending. She declares herself to be entirely normal in every way. She is never at a loss for a word; indeed, it was suggested that she was a trifle facile verbally. This patient has been in hospital for two long stretches, and great interest has been shown in her. She is naturally a friendly

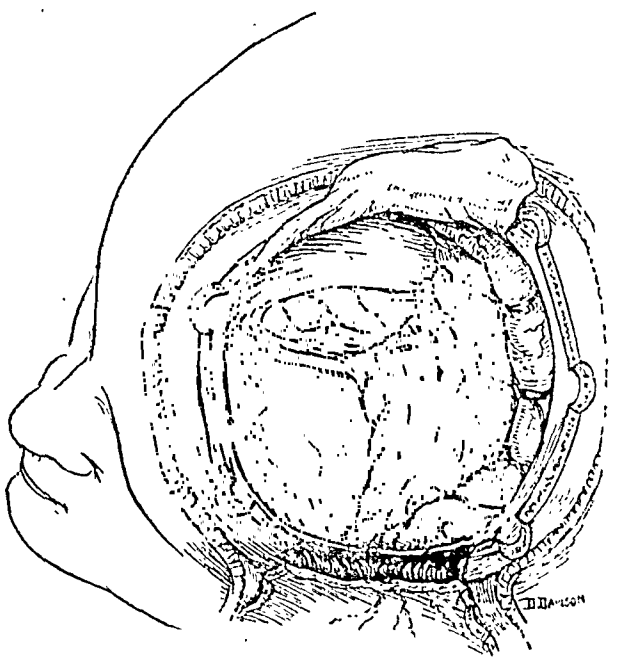

FIG. 1.—Left frontal lobe, subtotal removal.

person, and I am not convinced that her demeanour is different from that of any other individual who has had the same comparable experience in a special environment. Her pursuits at home are those normal to her social class: she reads the papers, goes to the cinema, listens to the wireless, and so forth. She has no difficulty in writing. She does not need to make shopping lists because she remembers all she wants. She has no difficulty with prices or money, and easily knows what change should be given her after her purchases. She is neither especially good-tempered nor especially bad-tempered. Possibly she is a little lacking in reserve, but, if so, this is scarcely noticeable. Views on that point will differ with the amount of deference that the observer expects, but patients of course are very variable in that respect.

Case 7

Mrs. B., aged 39, was referred on October 9, 1936, to the Neuro-Surgical Service of the Manchester Royal Infirmary by Dr. Leslie Cunningham of Liverpool with the diagnosis of left frontal tumour.

She had had headaches for over four years, usually left frontal. Two years ago she had an epileptic seizure, and she had had three since. They were severe, generalized, with unconsciousness for two or three hours. Nine months prior to admission she found that she was blind in the left eye, and for six months she had had anosmia. During the last year her memory had seemed to go, so that she found it very difficult to give a proper account of her illness. She thought that she did not always understand what was said to her, that she failed to catch the meaning, so that sometimes she did not do things asked of her or reply in a sensible manner. She had good insight into this failure on her part (as was so in Case 5), and it worried her. She was co-operative, but was inclined to facetiousness. She was not taking a gloomy view of her condition, but when this was mentioned to her she replied that she found little to be cheerful about. She knew that at times she was extremely irritable and difficult. She was much less active than formerly, and was inclined to sit about, but this she attributed to her bad eyesight and her headaches. On examination no grasp reflex was present and she was blind in the left eye. Bilateral consecutive optic atrophy was present with papilloedema. This and the anosmia were the only positive signs. Diagnosis had already been arrived at by Dr. Cunningham by means of thorotrast ventriculograms, which showed the anterior horns of the ventricles displaced to the right. Radiographs of the skull showed a normal sella and a large abnormal diploic vein on the left side in the parietal area which could not be directly related to the tumour. The pre-operative diagnosis was an olfactory groove, at least an anterior fossa basal, meningioma. Perhaps sufficient weight had not been given to the fact that she had only noticed her anosmia recently, quite three years after the onset of her troubles. On October 24, 1936, a left frontal flap was turned down. On opening the dura a dark, reddish-blue, voluminous glioma was seen occupying the left frontal lobe. It was adherent to the dura anteriorly and to the falx mesially. The superior longitudinal sinus and falx were resected for a distance of six centimetres in order to allow of block removal of the frontal lobe with its contained tumour.

The operation proved to be long and tedious; 600 c.cm. of blood followed by 500 c.cm. of glucose-gum solution were given at the end of two and a half hours, and at the close, an hour later, a further 600 c.cm. of blood. The tumour-infiltrated lobe was soft, very vascular, and difficult to handle, its adhesion to the dura being exceptionally dense. The right hemisphere was not invaded. Such areas of dura as were not easily removable and showed evidences of invasion were heavily coagulated with the endothermy unit. The line of section was clear except deep in and mesially, where the tumour changed colour and became pale. Perhaps this region represented an area of astrocytic reaction.

The patient's recovery was smooth. Except for extreme thirst she said she felt well enough. On the tenth day she became very excited and noisy, declaring that her children were outside the ward and were being prevented from seeing her. She was at that time quite out of contact and would not listen to reassurances or react to persuasion. She quieted with chloral and bromide, and next day was better. Three days later she apologized for the trouble she had given. She remembered the incident perfectly, and said that she had been mistaken in the date, believing it to have been the regular midweek visiting day. Her memory was better, and with the disappearance of her headache and slight improvement of her vision she became very much more normal. The tumour was found to be an oligodendroglioma.

The patient was re-examined on April 17, 1937, six months after the operation. She said that her memory was now remarkably good, and she gave a lot of details about her earlier history that she could not give before. For example, she told of an unreasonable outburst that she had shown seven years ago, which makes the history much longer than she had led us to believe. Except for a slight freedom of manner which was in no way unpleasant she appeared to be quite normal.

Case 8

Mr. L., aged 42, was admitted to the National Hospital, Queen Square, under Dr. Purdon Martin.

For five years he had suffered from attacks of minor epilepsy which he found difficult to describe; these were of short duration. Three years ago he had a major fit and was unconscious for half an hour. Two years ago he began to suffer from a frequent dull pain in the left forehead and around the left eye. For eighteen months his memory had been somewhat impaired for some recent things, whilst remaining good for older events. He is a cabinet-maker in his father's firm, and sometimes made mistakes in his measurements and forgot names. For nine months he had had visual impairment, the print going blurred on reading. On examination he was found to be a well-looking spare man, very slow in his reactions but well-mannered and very co-operative. There was anosmia on the right, none on the left (a paradox as it turned out). There was early papilloedema on the left, the right fundus being normal; fields were normal. There were no other positive neurological signs. Radiographs of the skull disclosed a series of confluent calcified rings low on the left frontal lobe, the inner edge just crossing the midline, no doubt below the falx. No such picture had been seen before, and it was suggested they might be calcified hydatid cysts. Whatever the lesion, it was clearly well delimited and benign, whilst it was equally certain that it was the cause of his complaints over the last five years or even longer (two undiagnosed illnesses in which he was unconscious for a varying number of days at long intervals, the first thirty-five years ago, have been omitted). The cerebrospinal fluid protein was 75 mg.

On December 23, 1936, the left frontal lobe was removed after the calcified mass had been enucleated from its interior. When the dura was opened there was seen to be marked atrophy of the anterior frontal convolutions, which were stained a dirty yellow colour. The convolutions felt very firm, and on puncture the calcified tumour could be reached at a depth of 1.5 cm. The main mass was mesial in position, so the veins entering the superior longitudinal sinus were coagulated to allow of inspection of the inner surface of the hemisphere. The tumour was then seen, and was shelled out of the left frontal lobe by dissection with wet pledgets of lintine. It had to be followed across the midline and the inferior longitudinal sinus and free edge of the falx divided to allow of its delivery from the opposite side. The anterior cerebral artery was closely adherent to the tumour and had to be cut; it gave some trouble before it was secured with silver clips. After removal of the tumour mass the shell of the left lobe which remained was seen to be so blue that it was thought wise to resect it. The operator already had had experience of two left-lobe removals to encourage him to do this. Moreover, the left anterior cerebral artery had been clipped near its origin, so that the lobe would be not only useless functionally but a likely source of trouble during convalescence. The left olfactory nerve was seen lying in the floor of the anterior fossa untouched by the tumour. The duration of the operation was two hours and twenty-five minutes.

The patient spoke at the end of an hour after the operation and gave his full name correctly. However, next day he was moderately aphasic, and during the next three days became disorientated, though his speech was better. He was incontinent. A week after the operation his incontinence had disappeared, his speech had returned to normal, and he was much clearer mentally. He made a steady recovery.

Two months after the operation he travelled down from Northampton by himself and went on to Bournemouth to a convalescent home. There he played cards with the other patients and took part in the ordinary routine. He was shown at the clinical meeting of the Neurological Section of the Royal Society of Medicine, February, 1937. He declared then that he was quite himself again; indeed, better and clearer-headed than he had been for some years. He was still slow in his manner and diffident, but he is that sort of person. A word should be added on the subject of his aphasia. He

was the only one of three cases of left lobectomy to show aphasia post-operatively, though it was of very short duration. The posterior end of the cyst-agglomerate extended well backwards behind the level of the lesser wing of the sphenoid and must have compressed the subcortical pathways well back. The disturbance was purely of "nervous shock" or diaschisis from oedema, for he recovered his speech in four days. This patient wrote to the hospital in April specially to thank everyone concerned, because he felt better than he had ever done before.

Amount of Cerebral Tissue Removed

The anatomical frontal lobe is the largest of all. It extends from the frontal pole to the fissure of Rolando, and includes the pre-frontal, frontal, and motor areas. No surgeon would remove the whole lobe, and in the cases described the frontal association "area" rather than the frontal "lobe" has been extirpated (see Figs. 2 and 3).

The lines of section have always had the same starting-point below, immediately anterior to the Sylvian point and the lesser wing of the sphenoid in order to avoid the middle cerebral artery and the insula. The incision has been carried from there up to the midline either straight or curving a little backwards. The areas of brain removed correspond to Brodmann's areas 8, 9, 10, 11, 45, 46, and 47. Area 8 has probably not been entirely removed in any of them (see Fig. 4). None of the cases had purely anterior polar removals. Of course it may be that with neoplasms the normal brain tissue has been pushed backwards to some extent so that the line of section is actually further forward than it seems to be. The surgeon can only record the state as he sees it at the time. More functioning cortex is removed with the gliomas than when the compressed brain tissue over a meningioma is taken away, so that the amount extirpated was probably least in Cases 4, 6, and 8. As for the actual technique, a lobectomy is by no means a difficult operation, and is often a preliminary to much more difficult procedures. The times taken over the various operations have been recorded, but they are only of passing interest. Some of the operations might well have been more expeditiously performed at the present time, though three were so difficult technically that saving time by cutting corners would have led to disaster.

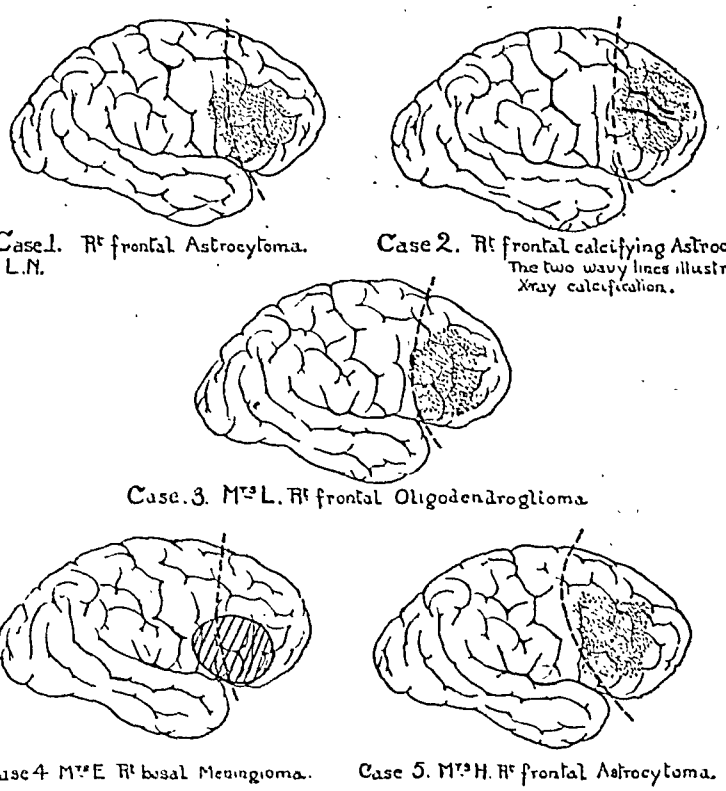

FIG. 2.—(Five cases).

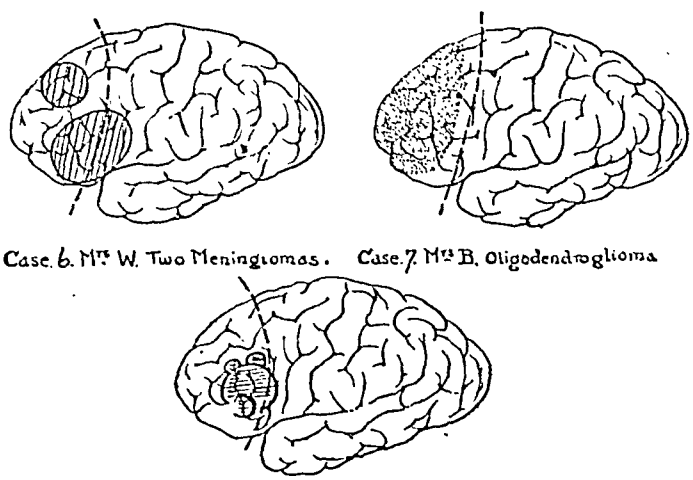

FIG. 3.—(Three cases).

Previously Recorded Cases

One of the earliest cases to focus attention on frontal lobe function was the famous "American crow-bar case" in 1848, which concerned a New England farm labourer, Phineas Gage by name. He was a popular hard-working man until his accident, in which a crow-bar 1¼ inches thick was driven by a gunpowder explosion completely through his head to fall on the rock near him. He was not unconscious, and walked away with assistance from the scene of the accident. After a severe infection which must have increased the cerebral injury he recovered so far as to be able to work at different places for twelve years, dying then in convulsions. Meanwhile he had had the foresight to sell his skull to several universities. It lies now in the Warren Museum at Harvard. Phineas Gage was converted into a "childish kind of crook (as Harvey Cushing has expressed it), was profane, obstinate, and given to outbursts of temper.

In view of the much more benign results of the frontal extirpations in the present series I have been at some pains to review this case. The crow-bar passed through the rostral end of the left temporal lobe, the left frontal lobe, the falx and superior longitudinal sinus, and the mesial surface of the right frontal lobe (see both Harlow's (1869) and Bigelow's (1850) descriptions and the skull itself). Such an extensive lesion is more in keeping with what follows and what has gone before than a sharply localized unilateral lesion would have been. However,

evidence drawn purely from traumatic material is apt to be fallacious, as we see next in Phelps's assertion (1897) that mental changes nearly always follow an injury of the left frontal lobe, rarely one of the right. In more recent times frontal lobe function has been studied by many writers. Grainger Stewart (1906) from his clinical observations denied the dominance of the left frontal lobe, and stated that mental changes were much commoner with bilateral frontal, and especially callosal, lesions than with those of one lobe alone. The present series

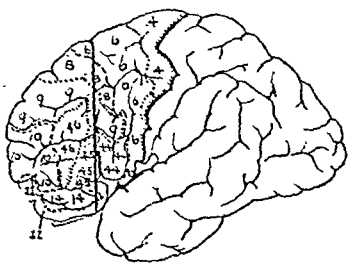

FIG. 4.—Diagram of frontal areas, Brodmann.

confirms that view. Animal experiments from the days of Goltz (1879) to Bianchi (1922), and on to Lashley, Franz, and Fulton and Jacobsen, have all pointed in varying degree in one direction—that unilateral removal of areas corresponding to those removed in my own cases led to no discoverable loss, whilst bilateral ablations did so (Fulton and Jacobsen, 1935). These two authors' ability to produce an "experimental hysteria" in anthropoids by giving them problems that were increasingly difficult to solve, and their inability to produce it after both frontal association areas had been removed because the animals were too easy-going to bother themselves when they failed, was an interesting side-light on the part played by these zones. It seems to be quite certain in experimental field work that anthropoids which have been largely trained beforehand are still quite able, after a single (either) frontal lobe has been taken out, to resume and solve the problems that they have learned, and even to add new ones to their repertory. Section of the corpus callosum on anthropoids has little or no untoward effect (Kennard and Walter, 1934), but clean section is quite another matter from callosal gliomas, which damage the lobes on the two sides.

Turning now to observations on removal of these frontal association areas in man, Dandy in 1922 described the operation of unilateral frontal lobectomy, and reaffirmed it in 1928 as a harmless procedure. He has not published analyses of the mental status of his cases, and detailed reports from whatever source are rare in the literature. In 1935 Penfield and Evans recorded three cases in detail, a fourth very briefly. One was of great validity, because the operator had known the patient intimately for forty years. All these patients showed surprisingly little deficiency after the operation; one was bad at mental arithmetic (but it may be doubted how far this can be widely applied as a psychological test), and one patient, the best-known case, was a little lacking in initiative, though able to do her housework and look after her family. In this patient, however, some growing tumour had been perforce left behind at operation, and she died subsequently of recurrence. German and Fox (1934) reported three cases with results much the same as Penfield's. Glen Spurling (1934) removed the right frontal lobe in the attack on an olfactory groove meningioma which crossed the midline, operating twice from the right side. Not only was the right frontal lobe removed, but the left was reduced to a fringe by the compression of the tumour. The actual degree of left-lobe destruction cannot be accurately estimated (see comment above on brain compression by non-invasive tumours). Spurling's patient made an excellent recovery, and psychometric tests by S. Ackerly (1935) showed her to be eventually near normal.

So much for unilateral and partial bilateral extirpations. One case only is on record in which both left and right frontal lobes have been excised in man—Brickner's case (1936). This is unique in the completeness of the post-operative analysis, only made possible by special circumstances. The record, though most instructive and exceedingly important, makes depressing reading, and no one surely will remove both frontal lobes widely again. A few remarks must be made about this case. A year and onwards after the operation he became a boastful, joking individual, with at the same time a certain amount of both voluntary inhibition, control, and synthesis of ideas. But in general he behaved like a child given to outbursts of naughtiness and difficulty, in which a sexual element was sometimes, but not always, present. Brickner states that his powers of evasion, when cornered on some point in argument, were little short of masterly. Studying this case, not alone in terms of brain removed but in the Jacksonian way, we come upon the question, With what parts of his brain were those jokes, those excuses, those mental side-slips, elaborated? Clearly with the more posterior portions of his brain. And Brickner, after exhaustive tests, concluded that there was no specific function in the frontal lobes which was not present in some degree elsewhere.

Discussion

Two points of great interest arise out of my own cases: first, that those who showed no mental alteration before the operation were unaffected by partial removal of the anatomical frontal lobe; secondly, that those who had mental symptoms were much better after the lobe had been excised. It can be concluded that removal of one frontal association area has left these patients with sufficient volume of neural tissue to ensure their being able to carry on their lives unaided afterwards (unless vision has been too badly interfered with by papilloedema beforehand). It appears to be quantity, volume, that matters most, even in man and not alone in the lower animals, as Lashley's work had suggested. No one will deny that the frontal lobes are deeply concerned in intellectual processes and emotional control, but they are not the only parts of the cerebral mass involved in these activities. It is clear that in a single frontal lobe mental activities have no closely packed, essential, or solitary locus the withdrawal of which leads to a state of dementia, partial or complete, and that the brain must function intellectually and emotionally as a whole, in the sense of Hughlings Jackson rather than in the departmental way that anatomical research once suggested. The frontal lobes cannot be regarded, either singly or together, as the "organ of mind." Pavlov proved the cortex to be a mosaic of function in which nothing was fixed except the motor and various sensory areas; it was a kaleidoscope of infinite possibilities of inhibition, adaptation, or substitution in mental and emotional processes. So that it can be concluded, from my own cases and those of others, that the reason why we have not known the exact localization of the higher cerebral functions is because they are not localized to any one small area.

Left-sided Dominance.—Many have thought the left frontal lobe to be more important than the right, and that

whilst right-sided lesions produced no great change left-sided ones did so. The evidence in favour of this is very tenuous, and my own cases go directly against such a view, for the patients were equally little affected, whichever side was operated upon. It must be conceded that once a lesion on the left side begins to go back behind the limit of the association area on the left there is a likelihood of damage to the speech centres, and no doubt it is on this account that the doctrine of left frontal dominance has grown up. An analysis of clinical material by Hyland and Botterell (1937) shows no essential difference between the two lobes apart from the aphasic element, and their conclusions on frontal lobe activities appear to be similar to those expressed here.

Cause of "Frontal" Changes

If a patient, one of whose frontal areas has been removed, has no severe frontal signs afterwards, it can be assumed that it was not purely one-sided frontal damage which was the cause of his previous disabilities. This is a very important point, but it seems to be established. In searching for another explanation two suggest themselves. The first is that it is the rise in general intracranial pressure occasioned by the tumour which is the additional agent that adds volume to the local lesion by producing widespread cerebral anaemia or oedema and interferes with the irradiation of impulses, compensation, inhibition, and so forth. Many cases are on record in which mental confusion has disappeared after a plain decompression without removal of a tumour. It must be that the successful operative management of such cases, with the consequent fall in intracranial tension and better cortical vascular irrigation, allows a resumption of normal powers by the uninjured parts of the brain. Conversely, frontal signs often appear in a high-pressure case even when the tumour is not frontal in situation. Gordon Holmes (1931) has expressed the opinion that mental symptoms are often due to high pressure irrespective of the site of the lesion. This is unquestionably true, and there is little doubt that many ill patients are psychologically abnormal not only because their suffering alters their reactions, but because their cerebral functions are impaired by anaemia. High pressure alone disturbs the mental activities of a patient more than does a local frontal tumour, because it interferes with the brain more widely than the tumour itself does; on the basis of Pavlov's view of cortical function in an integrated manner this can occasion no surprise. However, in the present series, in two cases the pressure was high and the patient had a frontal tumour as well, yet frontal signs were at a minimum. It is noteworthy that in both of these the tumour was non-invasive. This brings up the second possible factor already foreshadowed, the possibility of the tumour itself inducing some of the changes. We know that tumours which involve the primary receptor or effector apparatus often stimulate those areas to produce Jacksonian, motor or visual, or very often olfactory fits. Something of the same kind may occur in the frontal lobes; there may be some excitatory factor at the nature of which we can at the moment only guess. Such an idea was put forward long ago by Dupré and Devaux, who believed that the tumour exerts a toxic influence; but there is no clear evidence of it, and I, along with A. D. Macdonald, have failed so far to find histamine in gliomas in a few trials. I believe that the general circulatory basis plays a considerable part in the production of mental and emotional changes, but I am impressed by the differences shown by patients with invasive and non-invasive lesions. It should follow that "frontal" changes will be most pronounced when the lesion is bilateral (as in callosal tumours), or when it is invasive, or when pressure is high, or in combinations of these conditions. Moreover, it is now easier to understand the delirium of toxic conditions, general and local, and suggest new ideas in the interpretation of the various states arising out of head injuries.

It would be unwise to conclude that removal of a frontal association area will always be a benign procedure. The patients in this series were not of any considerable mental stature; their occupations were not such as would easily bring to light faults in the higher synthesis of ideas. Whilst, therefore, a considerable amount of caution must be exercised in drawing conclusions from them which would tend to the formulation of a dogma, they illustrate the more plastic conception of cortical activities current to-day. In none was the operation carried out except in the face of necessity.

ENURESIS*

BY

ROBERT HUTCHISON, M.D., LL.D., F.R.C.P.

Consulting Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond Street

It may be said of enuresis, as Bacon said of medicine in general, that it is a subject which has been "much laboured but little advanced," for in spite of all the attention that has been devoted to it we are still very ignorant of its causes and mechanism, and largely helpless in its treatment.

For the purposes of this discussion it will be well to define enuresis as "bed-wetting," although it is true that diurnal incontinence is often present as well. On certain points we shall probably all be agreed: that enuresis should not be regarded as abnormal until the child has reached the age of 3; that it is commoner in boys than in girls; that most cases date from birth, although occasionally bladder control is lost after it has once been acquired; that it is worse in cold weather. We shall agree also, I think, that the term "enuresis" should be reserved for functional cases and that examples of incontinence associated with diabetes mellitus or insipidus, with chronic nephritis, with stone in the bladder, and with congenital lower urinary tract obstructions should be excluded, as well as incontinence occurring in cases of epilepsy or mental deficiency.

* Read in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Belfast, 1937.

There may be less agreement as to the type of child likely to suffer from enuresis. Some are of opinion that it is commonest in children who are either highly excitable on the one hand or unduly phlegmatic on the other; my own experience has been that enuretics do not differ in temperament from the average.

As to the mechanism of the disorder there has been much speculation, but, broadly speaking, it may be said that the underlying defect is some failure in the neuromuscular mechanism of the bladder, so that the reflex micturition of infancy persists. Further than this very general statement I do not think one can safely go. It has been suggested that the failure is brought about by the cessation during sleep of the control exercised by the higher centres over the lower; but that surely is the case in every child, whether an enuretic or not.

Various contributory conditions or exciting causes have been put forward, some of which are of doubtful validity. I do not believe, for instance, that high acidity of the urine is a cause, and I am very doubtful about phimosis. Threadworms have been specially blamed by some, and their importance as a factor is worth discussing. On the other hand I am quite sure that adenoids and enlarged tonsils, especially if causing obstruction, may sometimes lead to enuresis—explain it as we may.

There is one interesting group of cases, however, which deserves special mention, a group small in proportion to the total number of enuretics, but perhaps larger than we think—namely, those in which the enuresis seems to depend upon a nocturnal polyuria, or, to put it in another way, upon a reversal of the normal relative amounts of day and night secretion. Such cases are not generally recognized, but they certainly exist. They may be detected either by actual measurement of the day and night urine or by finding that the specific gravity of the day secretion is unduly high, that of the night unwontedly low. To explain these cases is difficult. One is tempted to suppose that there must be a delay in excretion or some vasomotor factor at work, but these are matters we might well discuss.

There is likely to be some difference of opinion as to the part played by psychological factors in the production of enuresis. For my own part I have not found it commoner in difficult and "maladjusted" children than in others, and I confess I am not convinced of the reality of some of the alleged causes put forward by the extreme Freudians. It must always be remembered that those who work in child guidance clinics are seeing a selected material. They miss the sanifying atmosphere of the general out-patient department.

Prognosis and Treatment

As to prognosis it will be generally admitted that enuresis usually disappears before puberty, although its continuance into adolescence is all too common, and it persists even into adult life oftener than is supposed. When all allowance is made for the fact that it is commonly recovered from, it is none the less a real nuisance, for it may interfere seriously with the patient's education and choice of a career, besides being a great social handicap. As a French writer has put it, the enuretic is often "socially dead."

It is the question of treatment, however, which must chiefly interest us in such a discussion as this, and we must all, unfortunately, be convinced that there is no one plan which is sure of success; the very number of the remedies proposed is proof of this. It must also be noted that in a condition which may undergo sudden and spontaneous improvement and the severity of which is affected even by such extraneous circumstances as the weather, it is more than usually difficult to assess the value of any particular measure, and often enough the remedy which is being used when spontaneous improvement happens to set in gains undeserved credit.

General Management

As far as the general management goes there is not much room for difference of opinion. All admit the importance of a firm mattress, adequate bed coverings, and abstinence from the ingestion of much fluid in the later hours of the day. "Accidents" may be rendered less disagreeable by the wearing of a thick pad of sphagnum moss, and I have sometimes, in the case of adolescents, recommended the use of a rubber urinal such as is worn by patients suffering from incontinence the result of spinal paralysis.

The "taking up" of the child when the mother goes to bed is really only a way (I would suggest) of dodging unpleasantness. It cannot be really curative, for the normal child does not need to be so "taken up." None the less, it is a proper part of treatment.

Remote causes should be dealt with. By all means get rid of threadworms, although I cannot agree with some enthusiasts that they are the main cause of enuresis. I doubt if phimosis is worth dealing with, except on its own merits (or demerits), but I am convinced that I have seen cures result from the removal of tonsils and adenoids.

Use of Drugs

Among drugs belladonna has remained the most popular ever since it was first recommended by Bretonneau more than a hundred years ago, but its mode of action is ill understood. I usually give a dose about 5 o'clock in the afternoon and another at bed-time, gradually increasing the quantity up to a point just short of toxicity. It should be continued for some weeks and then gradually left off. Ergot also has a considerable reputation, although it is less used than formerly. It is difficult to see pharmacologically how it can do good, but I have had at least one case of the nocturnal polyuria type in which it seemed quite definitely to control the enuresis. Ephedrine has lately been recommended in a half-grain dose at bed-time, increased by another half-grain every week. It is said to act by increasing the tone of the sphincter whilst relaxing that of the bladder musculature. It will be interesting to learn the experience of anyone here who has tried it extensively. The endocrines, I think, will not help us much. A good deal has been claimed for thyroid in the case of the phlegmatic child with enuresis, but I consider the claims exaggerated. Pituitrin, from its antidiuretic action, ought theoretically to be useful, especially in the nocturnal polyuria cases, but it is an inconvenient substance to administer, and I have had no experience of it. I gather that those who have tried it have been disappointed with the results.

Psychotherapeutic Methods

The more heroic and semi-surgical procedures such as epidural injections, the passage of sounds, and so forth will, I imagine, be condemned by most of us, so we are left only with psychotherapeutic methods. As to the value of these there is considerable difference of opinion, although all are at one about the importance of creating the right psychological atmosphere for treatment by seeing that the disability is regarded in a common-sense and unemotional way and that the patient is not allowed to be either frightened or fussed. But can we do more than

this? Suggestion has been used in an endeavour to teach the child "to control the bladder during sleep." But can any child—or adult for that matter—be expected to exercise such control? Hypnotism I have never practised myself, and I have not been impressed by the results it has yielded in the hands of others. There is a form of suggestion for which success has been claimed in America and which consists in the weekly subcutaneous injection of 1 c.cm. of sterile salt solution. It is impressed upon the child at each injection that the treatment will certainly abolish the enuresis, but that if this should persist further injections will be required. For my own part I regard such treatment as a disguised form of punishment hardly to be distinguished from the use of the nurse's palm, and, besides, we should not lie to the young.

Of the more severe psychotherapeutic procedures such as Freudian analysis I cannot speak from any experience, but their use seems to me disproportionate to the object and rather like breaking a butterfly on the wheel. The value and limitations of this as of other methods of treatment in enuresis, however, it is one of the chief objects of this discussion to make clear.

CARE OF THE VOCAL CORDS IN SINGERS AND SPEAKERS*

BY

SIR MILSOM REES, G.C.V.O., D.Sc., F.R.C.S.Ed.

Laryngologist to the Royal Opera House, Covent Garden, and the Guildhall School of Music

In considering the care of the voice it will serve the purpose best if examples are drawn from experience with outstanding artists, just as, along other lines of achievement, one would take those who excelled in sport or politics. Therefore I shall point my moral by reference to some of the world's greatest singers as they have been heard from time to time at the Royal Opera House, Covent Garden, with which I have had a close connexion for over a generation. The same principles will apply to all who make exceptional use of the voice in their professions.

It is necessary first to ask, "What is singing?" and that opens up a previous question, "What is sound?" Sound is defined, from the physical point of view, as vibrations appreciable to the ear. Noise is the beating of the waves of air upon the ear-drum in irregular fashion, while in music the impingement is regular and periodic. In singing or speech the vibrations originate in an expiratory current from the lungs passing the edges of the vocal cords and setting them in motion, just as in the violin or other stringed instrument the pulling of the string creates the air waves and forms the note. The lowest audible vibration is 32 times a second; the highest, one of 76,000 times a second; but in music the vibrations employed range from 40 to 4,800, representing seven octaves.

In chest notes the entire length of the vocal cords vibrates, in head notes the length is shortened according to the note required. Falsetto notes are due to the false vocal cords situated immediately above the true ones acting as a damper on the outer part of the latter. The following table gives numerically the vibrations of the vocal cords for different voices:

	Vibrations per second	Average wave-length
Bass	87–256	12 ft.
Baritone	106–341	
Tenor	128–435	6 ft.
Contralto	160–512	3 ft.
Mezzo-soprano	192–640	
Soprano	Up to 768, occasionally higher	1½ ft.

The beauty and the carrying power of the voice depend upon the breath control, which produces the requisite vibrations of the cords kept in a properly tense condition by the nerves of the larynx, together with a proper posing of the voice to obtain resonance from the sinuses of the head, these acting as resonating cavities or sounding-boards and also amplifiers. The best voices naturally are those which have the most and finest elastic tissues in the cords. If the edges of the cords are viewed with the laryngoscope during singing they appear as sharp as razor blades in the great sopranos. Bad tuition produces tiredness and redness of the cords, overstretching of the elastic fibres, and occasionally the appearance of nodules, while exceedingly bad tuition may even break the fibres and cause minute haemorrhages.

One inexperienced teacher sent me his first twelve pupils, three of whom had torn vocal cords as a result of his curious methods.

Modern Singing

Modern singing as taught to-day started only two and a half centuries ago. When one bears in mind the very small percentage of the population who can sing in any sense that can be called singing, the much smaller percentage who can sing really well, the relatively few who take up singing professionally, the fewer still who make a success of it even after years of serious training and great expense, one is led to the conclusion that singing is not a natural endowment, that the vocal cords were not constructed by Nature for singing purposes. Singing is an acquired accomplishment, into the service of which have been pressed certain organs not intended for it. The same conclusion is suggested by the multitude of troubles that afflict even the best singers.

If this be true, then there is no such thing as a natural singing voice. I have never heard of a leading opera singer who had not been taught how to sing. Singing is an acquired art, and that being so it follows that with more definite methods of teaching, greater experience, some anatomical knowledge, and care of the vocal cords, the best voices are yet to be heard.

Although many of the suggestions in this paper apply to the speaking voice as well as to the singing voice, the demands upon the singer are much more critical. An advocate in a court of law may use his voice for five or six hours a day and for several days running with no congestion of the vocal cords. He may permit himself occasional declamation, but apparently his voice is as tireless as, one may hope, is the attention of his auditors. Singers, on the other hand, after a long and heavy opera are often thoroughly exhausted and quite unfit for any renewal of the effort next day. It must be remembered, of course, that they have to act as well as sing, that frequently they are heavily clad, and very generally have more than the normal allowance of flesh. But one has only to consider the immense number of vibrations of their vocal cords, and the force with which their voice is projected, to understand that during their performance they are like engines running at excessive speed. These high notes with heavy volume mean an enormous strain, with subsequent exhaustion.

* Read in opening a discussion in the Section of Oto-rhino-laryngology at the Annual Meeting of the British Medical Association, Belfast, 1937.

Conditions of Modern Opera

Modern opera is more exacting to those who take part in it than it was in the leisurely Victorian and Edwardian days. The aeroplane enables the tenor to fly from Munich, Rome, or Paris to Covent Garden in time for a rehearsal the day before the advertised performance. Frequently the change in a few hours from a dry and warm climate to the wet and cold conditions of London causes a slight catarrh, of which the ordinary member of the community would take no notice, but to the singer and his audience is of crucial importance. The position of the laryngologist in attendance is also onerous. He has to ask himself whether by simple measures he can get the great artist through his performance—a matter to be decided immediately, because in opera it rarely happens that should a breakdown occur another celebrity, knowing the particular role, is at hand to take his place. Last year at the beginning of the season the tenor in *Lohengrin* suddenly developed laryngitis. By a fortunate coincidence Herr Melchoir called at the Opera House at 7.30 that evening, and within less than an hour he was in borrowed costume taking the place of the other. But such happy accidents cannot be counted on in opera. When this last season opened in damp weather one after another of the singers became catarrhal, although all got through and were better next day. One artist even went through his performance with acute congestion of the middle ear. It may be mentioned that Dame Nellie Melba made it a rule to have her nose and throat cleansed each morning of her performance, and my friend the late Sir Edward Marshall-Hall found his brain clearer for having his nose and post-nasal space sprayed out each day when conducting his long cases. Such a method also helps the resonance of the voice, one of the principal qualities in voice production. It is not merely a question of regular vibrations of the cords, but in class singers it is the resonance which, when well produced, will distinguish the best from the good.

Sometimes the teacher of music will send a pupil to the laryngologist to discover whether he is a tenor or a baritone or she a soprano or mezzo-soprano. Again and and again teachers bring their pupils because of no improvement or, worse still, because of the obvious results of wrong production of the voice. It does not follow that because of a few successes all pupils should be taught alike. It is necessary for the laryngologist to have standards of voices and vocal cords in his mind, such as those of Melba, Patti, Schumann, de Reszke, Caruso, Tauber, etc., if possible. Ask these pupils to sing a few scales, or a few bars of one of their favourite tunes: or, if grand opera singers, a part of their next opera, especially after treatment. Jean de Reszke, whom I have no hesitation in describing as the greatest artist the world has ever heard, was originally a baritone. It was as such that he made his first public appearance in Venice in 1874. Then he retired for a period, during which his voice gained remarkably in the upper register, and when he made his reappearance in Madrid in 1879 it was as a tenor. From that time his great fame as a singer, especially in Wagnerian parts, can be dated. The consequence was that people with indifferent voices went to him during his many years as a teacher—he taught almost until the day of his death in 1925—in the expectation of being made into tenors. Some of them he sent over to me. Very few were genuine tenors—the majority were baritones, and would never be anything else—but all were desirous of becoming tenors, or of being able to boast that they had been taught by Jean de Reszke.

In the great operas, especially the German, practically all the tenors have baritone cords to enable them to carry on their tremendously heavy work, forcing their voices through perhaps an orchestra of 120. One has only to listen to the voice of a Siegfried—or a Brünhilde—bursting through a huge orchestra to realize the strain it must impose. Only a few can take such parts without injury to their cords. That is why singers, particularly tenors, have a very short singing life.

Another point to remember is the frequency of injury to the cords in sopranos. Melba, when near the end of her career, would very occasionally in the last act of *Faust* make an error in her production, and twenty minutes later a little mucous vesicle might have been noticed at the edge of one of her vocal cords, disappearing in a few days after rest and treatment. Tetrazzini had haemorrhages of the vocal cords on two occasions, due to a slight tearing of the fibres. Another trouble, found more especially in tenors, is the development of nodules that remain until the end of their career if they go on working, as they usually do, with insufficient rest and treatment. Yet another trouble is loss of elasticity of the fibres through overstrain by using the chest notes instead of the head notes in the high passages. This was particularly shown in the very outstanding tenor Saleza, who would have been more famous had his period not coincided with that of Jean de Reszke. Singers' voices inevitably deteriorate with age, though in this country that is perhaps less appreciated owing to the extraordinary fascination which old favourites continue to inspire. The British public always wanted Patti for as long as she would sing even "Home Sweet Home" when she was turned seventy.

Treatment

The laryngologist called to attend a singer has first to determine the nature of the complaint. It may be local or general, or both. Dismissing general or chest conditions, and confining ourselves to this department of rhino-laryngology, we find that of all local troubles by far the most common come under the head of catarrhal, affecting the nose, post-nasal space, pharynx, larynx, and trachea, or it may be only the nose and post-nasal space, or only the trachea. In this respect we are fortunate in that the vocal cords themselves are the last part of this delicate apparatus to be affected. If therefore the congestion of these areas can be reduced it may be assumed that the vocal cords will remain free. The procedure I have found most helpful is to douche the post-nasal space through the nose with an alkaline solution to which a little menthol is added. The pharynx also should be well sprayed. My usual procedure is as follows: I use an inhalation of No. 2 nebuling compound with a coarse vaporizer, and finally an inhalation through the nose, and likewise through the mouth, of kasemol in paroleine (K.P.) and menthol in paroleine (M.P.) 1 per cent. in equal parts. Before douching through the nose I spray the inferior and middle turbinate by means of a fine spray with a very small amount of 1 per cent. cocaine. My 1-oz. spray suffices for at least thirty patients; so the amount used is particularly small. Should the pharynx be in a chronic condition then a slight spray consisting of

R	Tinct. ferri perchlor....	ʒ ss
	Stovaine	gr. v
	Menthol	gr. v
	Sp. vini rect.	ʒ iii
	Glycerin	ʒ iii
	Aq. dest.	ad ʒ i

may be recommended. This mixture, which must be shaken before spraying, proves very useful in all chronic catarrhal conditions of the throat.

Should there be nodules on the cords the mixture should be sprayed direct on to the cords daily, and the patient himself should be instructed to practise inhalation of K.P. and M.P. through a coarse spray from four to six times each day. If the nose alone is congested the solution may be employed plus drops of a mixture consisting of stovaine, carbolic acid, and ephedrine, 0.5 per cent. of each in paroleine. When there is tonsillar trouble a thorough washing with the alkaline solution mentioned should be given, followed by any antiseptic which is favoured.

Tonsil Operations

A word may be added about the undesirability of operations on the tonsils in the case of established artists. These people have taken years of study to obtain their form of voice production. In a large proportion of cases a tonsil operation will bring about some alteration of the voice, and when deterioration of the voice eventually occurs, as it does naturally, it is very likely that the surgeon's intervention will be blamed. The largest tonsils I have ever seen were those of a world-famous tenor and of a world-famous contralto. The time for tonsillar operation, if this is advisable, is during the early period of training before the tone production has been permanently set. Removal of the inferior turbinates should be avoided in singers. Enlarged inferior turbinates should be treated with the galvano-cautery. Deviated septa, save in exceptional cases, should remain untouched.

Finally, the laryngologist in this special field has occasionally to deal with a type of patient of whom specialists in other branches of medicine are generally free. Acute stage fright is not unknown in all classes and callings, but when the patient is a prima donna the case becomes formidable. It does sometimes happen that a lady of repute in the operatic world who wishes to create a sensation does so, not by singing but by refusing to sing. The disturbing announcement is usually telephoned to the Opera House on the morning of the performance. It has the highly satisfactory result for the lady that her name is written large in the evening papers, but for the management it is a matter of grave concern. Even if another prima donna be nearer than the next capital she has to be solicited to sing; she is naturally reluctant to take another's place when she has had no previous publicity, and the very idea of being a substitute may offend her *amour propre*. The public, too, have to be considered. They have paid to hear one particular lady, and they demand a return of their money. To put on another opera means great difficulties in engaging fresh artists and chorus and obtaining scenery which may be under some railway arch miles away. The delicacy of the task of the laryngologist who has to give an opinion on the lady in question will be readily appreciated, as well as his courage in facing her wrath should he pronounce her fit to fulfil her contract—but as her arias remain unsung perhaps the story is better unwritten.

The Duchess of Portland has issued an appeal for "the many old trained nurses who worked for very small salaries in the past, and whose tiny savings were used to help relatives or dwindled away as they themselves became old and ill. Not many people realize that there are hundreds of them living in great poverty in lonely rooms, without enough food and warmth." Gifts, large or small, should be sent to the Duchess of Portland, c/o The Nurses' Fund for Nurses, 95, Dean Street, W.1.

THE OBSTETRICAL SIGNIFICANCE OF PELVIC VARIATIONS*

A STUDY OF 450 PRIMIPAROUS WOMEN†

BY

HERBERT THOMS, M.D., F.A.C.S.

(From the Department of Obstetrics and Gynecology, Yale University School of Medicine)

During the past decade the development of roentgenological methods for measuring the dimensions of the bony birth canal has brought about a revival of interest in pelvic architecture, particularly in its relation to childbirth. The present study of pelvic mensuration represents the findings in a series of 450 primiparous white women consecutively delivered at term (their children weighing 2,500 grammes or more) in the New Haven Hospital. The system of roentgen pelvimetry we have adopted is the so-called "grid method" (Thoms, 1933; 1935), which was developed in this clinic. In addition we have employed roentgenometry of the lateral aspect of the pelvis in many instances, and in the latter part of the series we have used a newly modified lateral technique as a routine (Thoms and Wilson, 1937). The observations extend over the past three years, and the group represents all the white primiparous women who during that time have been registered for pre-natal care prior to their delivery in the hospital.

Types of Pelvis

That the bony pelvis is subject to variations in contour is not a new concept. A half-century ago William Turner (1886; 1886a) emphasized the frequent occurrence of pelvic variations, particularly as related to the superior strait. This author divided pelves into three groups—namely, dolichopellic, mesatipellic, and platypellic types—according to the pelvic index—that is, $\frac{\text{A.P. diameter} \times 100}{\text{Transverse diameter}}$. Our own classification is based largely on that of Turner; however, we employ as a criterion the length of the antero-posterior diameter of the superior strait in its relation to the length of the transverse diameter. We suggest, therefore, that for clinical purposes there are four variations in which the majority of pelves may be grouped for classification. These are:

1. Dolichopellic or anthropoid type.—The antero-posterior diameter is longer than the transverse.

2. Mesatipellic or round type.—The antero-posterior diameter is equal to or only slightly less than the transverse (the difference never more than 1 cm.).

3. Brachypellic or oval type.—The antero-posterior diameter is between 1 and 3 cm. shorter than the transverse.

4. Platypellic or flat type.—The antero-posterior diameter is excessively shorter than the transverse—3 cm. or more.

On the basis of the length of the antero-posterior diameter these first three groups (which more commonly occur) may be divided for purposes of clinical use into large, average, and small pelves, as follows:

1. Dolichopellic type: A.P. diameter 14 cm. or more, large pelves; between 12 and 14 cm., average pelves; 12 cm. or less, small pelves.

---

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Belfast, 1937.

† This study was made possible through the Research Funds of Yale University School of Medicine.

2. Mesatipellic type: A.P. diameter 13 cm. or more, large pelves; between 11 and 13 cm., average pelves; 11 cm. or less, small pelves.

3. Brachypellic type: A.P. diameter 12 cm. or more, large pelves; between 10 and 12 cm., average pelves; 10 cm. or less, small pelves.

It is obvious that the above classification is chiefly useful in depicting the shape of the superior strait. In describing a given pelvis, therefore, it may be necessary to use additional terms—for example, such terms as "mesatipellic type with narrow forepart" or "dolichopellic type with funnel outlet."

In the present series, in addition to the roentgenometric procedures mentioned above we have employed external outlet pelvimetry as described by Williams (1931); vaginal touch in the determination, when possible, of the diagonal conjugate diameter; and the usual external measurements, interspinous, intercristal, intertrochanteric, and external conjugate diameters. With regard to these latter measurements, as I have pointed out previously (Thoms, 1934), we find no useful correlation between them and the actual superior strait dimensions as revealed by roentgenometry.

Incidence of the Various Types

The incidence of the above types of pelves in the series of 450 white women is given below.

	Large	Average	Small
Dolichopellic type occurred 70 times, or 15.5% ..	6	53	11
Mesatipellic „ „ 203 „ „ 45.1% ..	17	145	41
Brachypellic „ „ 156 „ „ 34.7% ..	27	110	19
Platypellic „ „ 21 „ „ 4.6% ..	—	—	—

It will be noted from the table that the mesatipellic or round type was definitely predominant. This is an interesting fact, inasmuch as in the past many authors have assumed that the brachypellic or oval type represented the normal female pelvis. The predominance of the mesatipellic type in previous similar studies has led me to believe that nature's pelvis is round and not oval, a fact which has been emphasized by Vaughan (1937) and discussed at length by myself in a recent article entitled "What is a Normal Pelvis?" (Thoms, 1934a).

Interesting also in this series is the incidence of outlet contraction as measured by the inter-tuberal distance. When this distance is 8 cm. or less such a pelvis is designated as funnel in type. The incidence is as follows:

Dolichopellic type	.. .. ..	21 times, or 31.0%	
Mesatipellic „	.. .. ..	38 „ „	18.7%
Brachypellic „	.. .. ..	30 „ „	19.2%
Platypellic „	.. .. ..	4 „ „	19.0%

The increased incidence of the narrow outlet in the dolichopellic type is not unexpected, inasmuch as narrowing of the side walls of the entire pelvis appears to be characteristic of this group.

Incidence of Operative Intervention

In surveying the history of the labours certain facts seem to be of interest, and these will be briefly considered. The incidence of operative intervention is recorded as follows:

Dolichopellic type	.. .. ..	11 times, or 15.7%	
Mesatipellic „	.. .. ..	37 „ „	18.2%
Brachypellic „	.. .. ..	31 „ „	19.8%
Platypellic „	.. .. ..	7 „ „	33.3%

These operations are divided thus:

Caesarean section ..	.. 13	Mid-forceps operation	
Version and extraction ..	3	Low or outlet forceps	

The incidence of the low or outlet forceps, sixty times in 450 labours, deserves comment, because many of these patients might have delivered spontaneously if spontaneous birth were an object in itself. We believe, however, that in many instances where the second stage is prolonged primiparous patients may be more satisfactorily delivered by this means. Some authors have used the term "forceps control" for this indication, which is a descriptive term and should perhaps be adopted.

The Caesarean sections, thirteen in number, may be grouped according to pelvic type as follows:

Dolichopellic type	.. ..	0 times, or	0% incidence
Mesatipellic type	.. ..	1 „ „	0.5% „
Brachypellic type	.. ..	8 „ „	5.1% „
Platypellic type ..	.. ..	4 „ „	19.0% „

Ten of the above operations were on patients with small pelves in which the indication seemed to be obvious disproportion. In three there was no pelvic indication, and the operation was performed for: (1) pregnancy complicated by heart disease; (2) transverse presentation with early ruptured membranes; (3) borderline small pelvis in an elderly primipara (aged 45). The incidence of operative procedure in the series again seems to emphasize that the round or mesatipellic type pelvis is nature's pelvis, for spontaneous birth has a greatly increased incidence in this type.

Breech Presentation and Occipito-posterior Position

Breech presentation occurred in the series as follows:

Dolichopellic type	.. .. ..	7 times, or	10%
Mesatipellic type ..	.. .. ..	6 „ „	2.9%
Brachypellic type ..	.. .. ..	7 „ „	4.4%
Platypellic type ..	.. .. ..	0 „	

The relative increase of breech presentation in the dolichopellic type (10 per cent.) offers ground for interesting speculation, and whether this increase will be found in a larger group remains to be seen.

The occipito-posterior position was observed in the following cases:

Dolichopellic type	.. .. ..	13 times, or	18.6%
Mesatipellic „	.. .. ..	22 „ „	10.8%
Brachypellic „	.. .. ..	13 „ „	8.2%
Platypellic „	.. .. ..	2 „ „	9.5%

In our clinic pelvic examinations during labour are in general limited to rectal touch. It is probably true, therefore, that many cases of high posterior position which subsequently undergo spontaneous rotation to anterior position remain undetected. The above figures represent cases of posterior position of the occiput in which there was no doubt of their existence in the examiner's opinion. The comparatively high incidence of occurrence in the dolichopellic group I previously emphasized in 1933 in a paper entitled "A Type of Pelvis Intimately Associated with Occipito-posterior Position" (Thoms, 1933a).

Mortality Statistics

In this series there were no maternal deaths; six foetal deaths occurred, and these are summarized as follows:

1. 4,000 gramme stillborn macerated foetus; cause of death unknown (low forceps).

2. Stillbirth associated with hydrocephalus, spina bifida, club-feet (mid-forceps).

3. 3,500 gramme foetus; death intra partum of patient with severe pregnancy toxaemia (mid-forceps); small mesatipellic type.

4. 4,059 gramme foetus, stillborn after version extraction in small brachypellic type pelvis.

5. 3,145 gramme foetus; died two hours after mid-forceps operation in very obese patient with uterine inertia.

6. 3,510 gramme foetus, stillborn following breech extraction.

It seems reasonable to assume that the first two cases have little or no association with the type of pelvis or method of delivery, and as far as this study is concerned a corrected foetal mortality should exclude these, and is then 0.88 per cent. The gross foetal mortality for the series is 1.33 per cent.

Conclusions

It seems obvious from this and other studies that we should reconstruct our views with regard to the so-called normal female pelvis as it occurs in our adult white female population. This is evidenced by the fact that in this series the oval or brachypellic pelvis occurred in but 35 per cent. of cases. The classification here proposed seems to be of real practical value in our experience.

The chief value of exact pelvimetry by roentgen methods is undoubtedly manifest in cases of suspected disproportion. In this connexion the lateral roentgenometric technique referred to is of great importance. This is particularly true in those cases where at the beginning of labour the foetal head remains high at the superior strait and in which disproportion may be suspected.

In conducting labour in the dolichopellic type of pelvis it should be remembered that the longest diameter of the superior strait is antero-posterior and that this antero-posterior lengthening in most cases extends throughout the bony birth canal. This knowledge should therefore be useful in the treatment of cases of persistent posterior position and in directing the course of the aftercoming head in breech delivery.

Finally, with such simple roentgenometric methods at our disposal their routine use in primiparous patients seems justified and likely to be of great service.

The annual international symposium organized by the Ligue Française contre le Rhumatisme will be held on October 9, under the presidency of Professor Laignel-Lavastine, and will be devoted to the subject of radio-active treatments in rheumatology. Physicians, radiologists, hydrologists, and surgeons who are interested in this subject are invited to attend. The papers will be published in the October issue of the *Revue du Rhumatisme* and sent to all the subscribers before the meeting. Reduced railway fare and free admission to the International Exhibition will be granted to members of the symposium. A detailed programme will be sent on application to Permanence de la Journée du Rhumatisme, 23, Rue du Cherche-midi, Paris VI[e].

TREATMENT OF TENNIS ELBOW*

BY

G. PERCIVAL MILLS, F.R.C.S.

Surgeon, General Hospital, Birmingham; Surgeon, Royal Cripples Hospital, Birmingham; Orthopaedic Surgeon, Birmingham Children's Hospital

"Tennis elbow" occurs mainly in tennis players, but occasionally in golfers, and more rarely in metal workers and amateur gardeners who use respectively the hammer and the trowel. There is practically never a history of injury—the pain comes on gradually during or after the favourite pastime. The most prominent symptom is pain on the outer side of the elbow when gripping, and this pain is usually much worse on gripping with the forearm pronated; indeed, the grip in the supine position is often painless. The pain may come on while grasping some trifling object like a tea-cup, which may even be dropped, but most characteristically it occurs only during indulgence in the favourite game. It may be merely a nuisance and noticed only on mishitting a back-hand shot, but in some cases the patient cannot even hold a racket. On examination there is nothing to see, but there is always a tender point, either exactly over the radio-humeral joint, on the epicondyle just above, or in the extensor group of forearm muscles. It may be difficult to locate the exact spot, but the patient can nearly always find it, and pressure on it will make him wince.

Physical Signs and Treatment

Of fifty-eight cases of which I have full notes the tender point was over the joint—front, back, or side—in thirty-two, the epicondyle in twelve, and somewhere in the muscles in fourteen; but the respective points are so close together that certainty as to the exact position is not always possible. As an example of this I would quote a case which I classified as of the muscular type and thought I could feel a bursa. At a subsequent operation the bursa was found to be a protrusion of synovial membrane from the radio-humeral joint. Clearly this should have been classified as the joint type. The only other physical sign is a slight limitation of extension at the elbow-joint, more evident and often only evident with the forearm pronated; this occurred in approximately two-thirds of my cases, and is, I believe, the essential indication for manipulation. It may be very slight and no more than a springy resistance to complete extension, which is not felt in the opposite limb. It may be so slight, in fact, that it can be overlooked. On two occasions I have noted no limitation of extension, but against my general rule have for some special reason tried manipulation. In each case I obtained further extension with a definite click, and in each case there was a quick cure. Any gross limitation of extension, such as could be measured with an arthrometer, would suggest a much more serious lesion than the condition we are considering. In cases which present this typical limitation of movement the tender point is usually over the radio-humeral joint (74 per cent.), less frequently over the epicondyle (26 per cent.), and never in the muscles themselves.

Cases with muscular tenderness are of an entirely different character. My practice has been to advise manipulation only in cases in which I found limitation of movement. The technique, which I described some years ago, is very simple. Under nitrous oxide anaesthesia

* Read in opening a discussion in the Section of Orthopaedics, including Treatment of Fractures, at the Annual Meeting of the British Medical Association, Belfast, 1937.

the elbow is forced into full extension with the wrist and fingers flexed and the forearm pronated. At the same time, in epicondylar cases firm pressure is made over the tender point with the thumb of the hand which is controlling the elbow. When this movement is carried out one of five things is observed.

1. The elbow comes straight with a click, which gives one the impression of something slipping in the joint (thirteen cases).

2. It comes straight gradually, with a feeling as if adhesions were giving way (seven cases).

3. It gradually comes straight with continued effort, but neither click nor adhesions are felt (seven cases).

4. As soon as the patient is under the anaesthetic the elbow comes straight without the slightest resistance (three cases).

5. The elbow cannot be got straight (one case). This, of course, was a failure, and will be referred to later.

The routine after-treatment is simply two weeks' rest from tennis or golf, during which time the patient is instructed to maintain by daily exercises the extension that has been secured.

Results

Of thirty-three cases so treated twenty-two were cured within a fortnight; one was improved and could play tennis at once, but was not perfectly right for six months; three others took two, three, and four months respectively. Some of the cases were dramatic. One patient, for example, could not write, and on coming round from the anaesthetic he sat down and wrote me out a cheque, and naturally we were both impressed. A large number of the cases occurred in doctors and personal friends who would not hesitate to let me know if I had failed; in fact, the frequency of the condition among doctors has been a little disconcerting from the purely financial point of view. So much for the good side of the picture. Of the remaining seven cases three were apparently cured but subsequently relapsed, and these must be considered individually. One neglected his fortnight's rest and relapsed suddenly within that period; he was a medical man and insisted on a second manipulation, which cured him. One relapsed in five weeks, and the opposite elbow also became affected; this was probably an early general arthritis which I had overlooked. One relapsed in three months: he was 51 years of age, and gave up tennis.

Of the remaining four cases one has not been traced, and though the immediate result was satisfactory I should not like to call it a cure; the other three were utter and complete failures. One of these was an abnormal case, for, though there was pain in the elbow and limitation of extension, there was absolutely no pain on gripping. The diagnosis in this case was probably incorrect, but the patient came from a far Northern town and I have had no opportunity of seeing him again. The second case should have been a cure: there was limitation of extension, which corrected with a click, and when I saw the patient a month later movement was complete. However, he still had his pain, and this case I cannot explain. The third case in which I failed is more interesting; this was the one referred to above in which I did not succeed in forcing complete extension. This patient went to Blake in London, who also failed. A year later he was cured by manipulation by the trainer to one of our local football clubs. He very kindly told me all about it, and it is clear that the trainer succeeded in securing full extension, which both Blake and I had failed to do.

It appears, therefore, that, taking limitation of extension as an indication for manipulation, twenty-seven cases out of thirty-three were cured, and one other was subsequently cured by manipulation elsewhere. During the same period six cases were seen in which manipulation was advised but for some reason was not carried out by me. The ultimate fate of these cases is interesting in view of the possibility of spontaneous recovery. I have succeeded in tracing five. Three when last heard of were still unrelieved: one had the manipulation done by an osteopath and was cured, and one recovered after a few weeks' rest and massage.

Conclusions

We are justified in saying, therefore, that when the typical syndrome is present spontaneous cure is unlikely, and that manipulation gives an immediate cure in two-thirds of the cases and a slightly delayed cure in another one-sixth, making five-sixths in all.

Cases with muscular or epicondylar tenderness and no limitation of movement are in quite a different category. Some of them are suffering from what, to conceal our ignorance, we call muscular rheumatism or fibrositis, and the part which is over-used is naturally affected first. They soon show lesions in other parts of the body. I have seen three cases which started as apparent tennis elbow and subsequently developed a generalized fibrositis. Most of the muscular cases, however, are simply the result of overstrain, and a prolonged rest is the best, though far from welcome, treatment.

Pathology

I have left this to the end because it has to be deduced from the results of treatment. I believe that the common type of case with joint tenderness and limitation of extension is due to a fraying of the thin edge of the coronary ligament and the nipping of a semi-detached portion between the bones. My reasons are as follows:

1. The condition is frequently cured dramatically by a manipulation which produces a click.

2. It may relapse suddenly and be cured by a further manipulation. This happened to a medical man, referred to above.

3. In a case treated without anaesthesia the patient was certain that something had slipped back into place. He came to me in the middle of an important tournament and said he could not even hold a racket. A few hours after manipulation I watched him play a fine game.

4. On one occasion I opened the radio-humeral joint and found the thin edge of the coronary ligament frayed out as I have suggested.

5. The similarity to a displaced internal semilunar cartilage is very striking. Curiously enough, my manipulation for tennis elbow is exactly analogous to Sir Robert Jones's manipulation for reducing a knee cartilage.

I believe, therefore, that the dramatic cure that occurs in some cases is due to the freeing of a frayed edge of the coronary ligament which has got displaced between the bones. Cases with epicondylar tenderness are also often cured by manipulation, always provided there is limitation of movement, but I have noticed that it is seldom so dramatic as in the joint type. Patients often say that the elbow felt better from the first, but that it was a few weeks or months before it became quite right. I can only suppose that some tense bands, which were painful on being stretched, are ruptured completely by the manipulation.

Clinical Memoranda

Succinic Acid Treatment of Diabetic Ketosis

Dr. Korányi and Professor v. Szent-Györgyi have just published an important paper on their successful treatment of diabetic ketosis by succinic (amber) acid administered by mouth (*Dtsch. med. Wschr.*, 1937, **63**, 1029). With the chemical theory which they advance to explain its action we are not at present concerned, but with the five cases successfully treated the province of diabetic therapy is immediately involved. In four severely ketosed insulin cases the records, which read convincingly, show that, even after the omission of insulin, 10 grammes of succinic acid by mouth removed all ketosis in two to three days and much smaller doses subsequently prevented any recurrence of acetone bodies in the urine. Hyperglycaemia and glycosuria were scarcely at all reduced. A fifth case gave less definite results. From their clinical experiences they seriously suggest the possibility of treating severe diabetes with succinic acid instead of with two or three injections of insulin a day. At the same time they think their results need confirmation by other workers.

Unfortunately an English newspaper published in June the hopes raised by this new oral treatment—even before the above scientific paper was produced. Since then we have been mildly pestered by patients wanting the new amber acid instead of insulin, and we feel that we should publish at once the *completely negative and clear-cut results* we obtained on two patients in June. This experimental trial was undertaken at the suggestion of the Medical Research Council, who were requested by Professor Szent-Györgyi to give the treatment a trial. Two elderly women were chosen for the experiment; both showed a heavy ketosis and were judged to require insulin treatment as diet had failed to control the diabetes.

CASE RECORDS

Mrs. A., aged 64, had suffered from pruritus vulvae intermittently for two years, and an acute thirst for only two weeks. She was thin and wasted. Mrs. B., aged 59, had had diabetes for four years which had been treated intermittently by restricted diet. Her large face and hands suggested acromegaly: a radiograph showed a much enlarged pituitary fossa, so that her condition was presumably a type of pituitary diabetes.

On admission to hospital, after a period of dietetic treatment as out-patients, both women had a hyperglycaemia of from 220 to 300 mg. per 100 c.cm., and excreted constantly between 3 and 5 per cent. of sugar in all five samples of urine tested daily. The ketosis was uniformly heavy, Rothera's nitroprusside test being deep opaque purple (+++) and Gerhardt's ferric chloride test giving a faint positive reaction in about half the specimens passed. Throughout, the degree of ketosis was judged by these two tests and no quantitative estimations were carried out.

On admission both patients were kept in bed and placed on a diet of 100 grammes carbohydrate, 75 grammes protein, 150 grammes fat, and this was unchanged. The ketosis remained constant for three days, and treatment with succinic acid was then started. Doses of 10 grammes, the biggest dose suggested by the above authors, were given for one week, in capsules to one patient, in liquid form to the other, who could not swallow capsules. The ketosis became progressively heavier and the Gerhardt test changed to a deep red colour (+++) in every sample passed. The hyperglycaemia and glycosuria were unaltered. At the end of a week it was clear that the ketosis was getting progressively worse rather than better, and insulin treatment was begun and, as usual, rapidly removed the ketosis.

The only real difference in experimental conditions between *the four successful reported* cases and our two failures was the fact that in the former cases the patients had been on insulin before the experiment and ours had not. The diets used were not so materially different as to explain the opposed results. Four successful cases and two failures prove nothing. But it is clearly too soon to advise the treatment of diabetic ketosis with succinic acid instead of insulin.

Two Cases of Perforated Peptic Ulcer

The recent commentary in these columns on gastric perforation in a tabetic (March 6, p. 497) prompts me to record two further cases of perforation.

CASE I.

A man of 50, who had been drinking heavily for some time, had an acute attack of abdominal pain while in a public-house. He managed to walk home, and when I saw him two hours later was a little drunk and complained of pain above the pubes and in the penis. His temperature and pulse were normal, and there was no rigidity of the abdomen. In view of the pain he mentioned I passed a catheter and withdrew a few ounces of normal urine. He gave a history of indigestion for the past few months, but he had not vomited at the onset of the attack. There were no other signs or symptoms.

Three hours later he was in coma. His pupils were dilated, his face flushed, his breathing stertorous, his reflexes absent: *he gave the impression of a man deeply anaesthetized.* While I was preparing to carry out gastric lavage, on the assumption that it might be a case of alcoholic coma, he died. Post-mortem examination showed a large perforation on the lesser curvature, with the peritoneal cavity full of fluid which had once been beer.

The unusual features were the absence of rigidity, tenderness, and localizing signs, and the very short period—about six hours—between perforation and death. It seems possible that these are due to one factor—namely, the sudden release into the peritoneal cavity of a large quantity of alcohol. At first it acted as an anaesthetic, masking the pain and preventing the rigidity, while later it paralysed the central nervous system and caused the man's death.

CASE II

A man of 37, while working as a labourer, was seized with acute pain in the right hypochondrium of such severity that he fell down. An hour later he was pale and shocked, with a subnormal temperature and a pulse of 100, and still in great pain. There was an area of tenderness and rigidity in the right hypochondrium, but nowhere else. There had been nausea but no vomiting at the beginning of the attack, and there was no history of indigestion at any time.

After an hour's observation the area of tenderness had increased. At operation I found a small perforation of the duodenum, about a quarter of an inch in diameter, surrounded by an indurated area about an inch across.

The point of interest here is the complete absence of any previous symptoms. It is difficult to realize that ulceration can proceed to the point of perforation without giving any pain. I have questioned this patient further, and he still maintains that he "does not know what indigestion is." Right up to the time of his perforation he could eat and enjoy anything that was placed before him.

Reviews

DICTIONARY OF PATHOGENIC BACTERIA

Dictionnaire des Bactéries Pathogènes pour l'Homme, les Animaux, et les Plantes. By Dr. Paul Hauduroy, Dr. G. Ehringer, Professor Ach. Urbain, Dr. G. Guillot, and Dr. J. Magrou. (Pp. 597; broché 120 fr., relié toile 140 fr.) Paris: Masson et Cie. 1937.

In this dictionary of pathogenic bacteria by Hauduroy, Ehringer, Urbain, Guillot, and Magrou some 650 organisms have been described, embracing all those bacteria which have been found to be pathogenic for men, other animals, and plants. The book thus has a wider appeal than a purely medical one. The nomenclature followed is that of the American Society of Bacteriologists, the various synonyms being included, and the orders, families, genera, and species within the genus are arranged alphabetically. Since there are probably still some bacteriologists who are not thoroughly familiar with the American classification, a summary of this in chart form at the beginning of the book would have been a useful addition. In a volume of this size the description of individual species is necessarily rather brief, and the space alloted varies to some extent with their importance as a cause of disease. However, the main morphological, cultural, and fermentative characters of the different bacteria are adequately described, but at times serology does not get the full treatment it deserves. In these days when antigenic analysis has attained such prominence and its application in the identification of human pathogens has become so far-reaching, this aspect of the subject might have received more attention. For instance, the many varieties of streptococcus which have been named from time to time are considered under separate names, and no doubt the information given would enable a label to be attached to any given streptococcus. But the use of serological methods probably indicates a more useful separation of the genus into species and types, and this procedure is now receiving greater recognition.

The volume has a useful appendix, which sets forth the antigenic and biochemical reactions of the *Salmonella* as defined by the subcommittee of the Commission on Nomenclature of the International Society of Microbiology. The serological and biochemical reactions of the dysentery bacilli are also recorded here, and in five further tables the metabolic activities of six genera of Gram-negative bacilli are set out in such detail as to allow of differential diagnosis. This book should be of use to the bacteriologist more particularly in the tracking down of the less common species of bacteria encountered in the course of general bacteriological work.

MIDWIFERY IN THE TROPICS

A Textbook of Midwifery in the Tropics. By V. B. Green-Armytage, M.D., F.R.C.P., F.C.O.G., Lieut.-Col. I.M.S. (ret.), and P. C. Dutta, M.B., F.R.C.S.Ed., Capt. I.M.S. Second edition. (Pp. 447; illustrated. 12s. net.) London: Butterworth and Co. (India) Ltd. 1936.

The fact that a second edition has appeared within four years is proof that this book was needed and is appreciated. The staccato style and the manner in which the book is written are not only convenient for students studying in a foreign language, but allow of much material being compressed within a relatively small compass. Very little space is devoted to theory, and in these days of composite authorship the didactic dogmatism is welcome and refreshing. The chapter on diseases associated with pregnancy is concise and adequate, but it is surprising that typhoid fever is not accorded a single paragraph. There are many, particularly in America, who will not agree with the advice to give women in malarious districts 6 grains of quinine daily throughout pregnancy. It is surprising that the authors do not advocate the routine instillation of silver nitrate drops into the infant's eyes, and it is disappointing that they make no mention of rectal examinations, for there is no need, as implied, to make a vaginal examination to discover whether labour has begun. One other criticism must be made, and that is the freedom with which Caesarean section is advocated. Not only is it advised in cases of "failed forceps" associated with occipito-posterior position, but in the section on uterine inertia complicating breech presentation the following sentence occurs: "It is better to do Caesarean section than lose the child." Such treatment may possibly be best in the authors' hands, but would appear to be dangerous teaching in a textbook for students.

This is an excellent book, remarkably free from typographical errors. It contains a surprising amount of information, and is to be heartily commended not only to students in India but also to those in this country.

TREATMENT OF INFANTILE PARALYSIS

Infantile Paralysis and Cerebral Diplegia. By Sister Elizabeth Kenny. (Pp. xxviii + 121. 21s.) Sydney: Angus and Robertson Ltd. London: Australian Book Company, 37, Great Russell Street, W.C. 1937.

Even if the development of paralysis in acute anterior poliomyelitis could be prevented, the grave problem that this disease presents would not be completely solved. There would still be many cases in which the condition escaped recognition in the earliest stages and which progressed to frank paralysis. Treatment of the established condition will, therefore, for long remain an important consideration. Treatment during the stage of recovery may be summarized as follows: splinting of affected muscles in a position of relaxation from the first; physical treatment begun four to ten weeks after the acute onset, the most important item being graduated exercises; strict recumbency in all cases where anti-gravity muscles are involved; treatment to be continued until recovery is maximal. Unfortunately it is found that a certain number of cases, treated carefully from the first, show very incomplete recovery, and the permanent disability is sometimes serious. Anyone who has had experience of such cases would welcome a new form of treatment that gave uniformly good results. The anguish of the parents of a splendid child who has been stricken with paralysis is not easily forgotten, and it is a sad business to talk to them when it has become apparent that more or less permanent paralysis is certain.

Sister Elizabeth Kenny of Queensland has evolved a system of treatment for which astonishing results are claimed. It has aroused interest and controversy in many parts of Australia, and is now the subject of an investigation in the Commonwealth by a Government Commission. Her methods are described in a book entitled *Infantile Paralysis and Cerebral Diplegia.* She defines the general principles for the treatment of poliomyelitis as follows: (1) maintenance of a bright mental outlook; (2) maintenance of impulse; (3) hydrotherapy and remedial exercises; (4) maintenance of circulation; (5) avoidance of the generally accepted methods of immobilization. The remedial exercises differ little from those usually employed, except that they are begun during the acute stage of the disease and given with great frequency. It is the abandon-

ment of splinting and rest in recumbency (all of which work has been done at out-patient clinics) that is so startling. It is apparently unnecessary to rest a paralysed deltoid by fixing the arm in abduction, or the abdominal muscles by keeping the patient in bed—a complete denial of accepted physiological principles.

But it is the results that matter. Sister Kenny has been responsible for the treatment of about 600 patients, and a small number of them were investigated by a surgeon, Mr. J. V. Guinane. He states that all recent cases have been totally and permanently cured and all long-standing cases have been improved. It is safe to say that such results have never before been reported, and the reader will look eagerly for detailed reports on typical cases. There are none—not a single complete history and no muscle charts. It is this that makes Sister Kenny's book so disappointing, for it is robbed of much of its scientific value through the absence of documentary proof of results that it is the bounden duty of a scientific writer to produce when special claims are made for a new form of treatment. For the same reason we cannot profitably prolong this review. It would have been necessary to examine the conditions under which observations were made, the nature of the controls, and the question of trick movements. Sister Kenny may rest assured that in spite of her departure from widely recognized principles (in the treatment of infantile paralysis) her work will receive sympathetic attention in this country. Let us hope that the official report of the Commission in Australia will be entirely favourable, for no one can be satisfied with things as they are now.

AIR RAID PRECAUTIONS

If Air War Comes. A Guide to Air Raid Precautions and Anti-Gas Treatment. By L. Haden Guest, *M.C.*, M.R.C.S., L.R.C.P. Foreword by the Right Hon. Viscount Dawson of Penn. (Pp. 88. 1s. net.) London: Eyre and Spottiswoode. 1937.

Gas, A Synopsis of Defence Against. By John Fenton, M.B., B.Ch., D.P.H. (Pp. 52. 1s. net.) London: Dale, Reynolds and Co. 1937.

If Air War Comes is a sensible book on a very difficult subject. Works on defence against air raids divide themselves into two classes—those written by persons with experience of war and those written by persons without such experience; Dr. Haden Guest's belongs to the former. He gives a reasonable estimate of the amount of damage likely to be inflicted by air raids. He does not underestimate the horrors of such attacks, but points out the measures which will reduce the casualties as low as possible. The volume is of special importance because the author has been medical instructor to the Air Raid Precautions Department of the Home Office. The chapter of special interest to the medical profession is that on "Doctors, First Aid, and Hospitals." Two of the most important passages in the description of the functions of first-aid posts are as follows: "It is clear from this short description that the success of such decontamination centres will depend on proper order and discipline being maintained . . ." and "Many cases will flock to the first-aid post although they do not require treatment. There will be people instinctively seeking shelter and aid in their distress, friends of the injured or gassed, or those affected by such comparatively innocuous agents as the tear gases and the nose irritants." These sentences indicate one of the possible dangers connected with first-aid posts—namely, that they may become death traps by being congested with unmanageable crowds of people, some of whom are contaminated with mustard gas. In general it is of interest to note that the author considers that mustard gas has maintained its evil pre-eminence as an injurious agent. He estimates that twelve pounds of chloride of lime is necessary for the decontamination of one square yard of road surface. The book only costs a shilling and gives a clear and sensible account of how to reduce the dangers of air raids. It therefore deserves a wide circulation, particularly among the medical profession, who will have a task of exceptional difficulty and danger in the event of air raids.

Dr. John Fenton's Synopsis of Defence against Gas is a pocket volume of condensed information. It contains the notes of courses of lectures given to first-aid organizations, and should be very useful to those attending such courses.

DERIVATIVES OF MILK

Milk Products. By Wm. Clunie Harvey, M.D., D.P.H., and Harry Hill. (Pp. 388; 73 figures. 16s. net.) London: H. K. Lewis and Co. 1937.

The surplus cow's milk produced in this country presents a difficulty for which remedies have been suggested. One plan has been to endeavour to develop a right appreciation by the people of the merits of the fluid. But as the general attitude towards these efforts has been on the whole inadequately responsive, producers have turned their attention to the manufacture of milk into milk derivatives of various kinds. Many of these preparations have deservedly won favour and are being widely consumed in substantial quantities. For these reasons an acquaintance with the manufacturing processes involved has become indispensable to sanitary officers placed in charge of the purity and soundness of the foodstuffs used in their areas.

Useful guidance in this matter is supplied in the book issued by the medical officer of health and the sanitary inspector of the borough of Southgate. In the opening section, which is on ice-cream, the authors note that the substance was introduced into Britain by an Italian in 1860. Up till the time of the European War the business remained largely in the hands of the small producer and the itinerant vendor. Then America awoke to the charm of the delicacy and introduced mechanical plant for its production *en masse*, with the result that it is now a staple article of diet in that country. Following an account of the food value of the product, its bacterial content, and the communicable diseases to which it has on occasion given rise, the authors set forth the methods of production of ice-cream on both the small and the large scale, illustrating them by means of informative drawings and photographs. The procedure for the chemical and bacteriological examination of ice-cream is next detailed, and there is an ample citation of the English general and local statutes bearing upon the control of sales. Reference is made also to procedure regarding ice-cream in Australia, the United States, Holland, and Belgium.

Under the title "Cream," as distinguished from ice-cream, the topics dealt with by the authors include the properties and composition of cream, the breed of cow, the transmission of disease, separation by hand and by machinery, bacteriological and chemical examination, the use of the Hortvet cryoscope, and methods of legislative control. Under the title "Butter and Margarine" food values are considered and the theory and practice of the manufacture of butter are discussed. Faults in flavour and appearance receive due attention, and the chemistry and bacteriology of butter are adequately presented. Whey butter, milk-blended butter, and what is known as "reno-

vated" butter are referred to also. The manufacture of margarine and the legislative control of both substances conclude this section.

The subjects of the remaining sections, which are equally comprehensive, are cheese, condensed milk, evaporated milk, dried milk, and subsidiary milk products. The work concludes with an interesting note on three recent uses of milk: (1) in the form of dried cubes; (2) as an ingredient of a cement for ships' tanks; (3) in Italy as a source of artificial wool.

MALIGNANT TUMOURS OF THE NOSE AND NASAL ACCESSORY CAVITIES

Maligne Tumoren Van de Neus en Neusbijholten. By Hermanus Claassens W[illegible]. (With 30 illustrated.) Groningen: J. B. Wolte[illegible]. 1937.

His thesis for the degree of doctor of medicine of the University of Groningen, on malignant tumours of the nose and nasal accessory cavities, has been published in book form by Dr. Hermanus Wykerd. The thesis is written in Dutch, so that the text is not available for most English readers, but there is an excellent summary of seven pages and a good bibliography. The author draws attention to the remarkable frequency with which squamous-celled carcinoma occurs in a region covered with columnar epithelium. It is claimed that the majority of malignant tumours originate in the antrum. This is based on thirty-five cases observed at Groningen. There were twenty-five cases of carcinoma and ten cases of sarcoma. The antrum of Highmore was the seat of origin of the tumour in twenty-two cases, the nasal cavity proper in six cases, the frontal sinus in five cases, the sphenoidal sinus in one case, and the nasal septum in one case. This distribution is very different from the usual experience, which would give a high place to the ethmoid, not mentioned in this series.

The cases have been carefully studied both pathologically and clinically and the conclusions follow fairly closely those reached by Öhngren at Stockholm. Five of the patients are alive, free from recurrence for three and a half to eleven years. There are some interesting photomicrographs showing how Paget's disease, epulis, and osteitis fibrosa all produce a similar growth in the nose, resembling giant-celled sarcoma. As a special study the thesis forms a useful work of reference on numerous points.

Notes on Books

A second edition of *The Evolution of the Endurance, Speed and Staying Power of the Racehorse*, by Dr. W. J. STEWART MCKAY, has been published at 7s. 6d. by Hutchinson and Co., London. In addition to his eminence on the Australian turf the author has many publications on agriculture, zoology, veterinary medicine, and human surgery in his name. A history of the evolution of the racehorse, occupying the first half of the book, apparently leads Dr. McKay to the conclusion that in the great majority of cases the staying power of the racehorse is inherited from the sire. In the second half Dr. McKay reveals how long observation on the course, intimacy with racing records and stud books, and gleanings from physiology have convinced him that the failure of a horse in its races is due to cardiac insufficiency. Though his medical and veterinary colleagues may search in vain for the measurements of racehorses during life and after death, supporting the author's "heart theory of staying power," they may be thrilled with the chapter explaining how to follow form and spot the winners. Obtaining such information direct from the horse's mouth, the sportsmen and trainers, for whom the book is intended, will revel in the author's description of the genes, hormones, cardiac outputs, and other queer things in their bloodstock. Thus the book provides something for everybody.

A second edition of Dr. GLADYS M. COX'S *Clinical Contraception*, with an introduction by Lord Horder, has been published by W. Heinemann (Medical Books), Ltd., at 7s. 6d. This book was written in the first instance at the suggestion of the National Birth Control Association. The new edition emphasizes the author's conviction "that the use of a *combination* of a chemical and a mechanical contraceptive, selected for the individual patient, gives the greatest possible security against conception. The claims made by the manufacturers and distributors of the absolute reliability of certain chemical contraceptives cannot be substantiated clinically."

The richly documented work on *La Tosse* (Palermo: L. Salpietra, 30 lire), by Dr. ANTONINO CULOTTA, assistant to the Institute of Morbid Anatomy of Palermo University, is, as its subtitle indicates, divided into three parts, devoted respectively to the physiopathology, clinical aspects, and treatment of this distressing symptom. In the clinical section cough is considered first as a symptom of respiratory disease, and secondly as a manifestation of disorders of the digestion, cardiovascular, and nervous systems, diseases of the lung and kidneys, and acute infections. A bibliography of 173 references is appended.

Preparations and Appliances

"P.B.A.S."

P.B.A.S. (Hewlett's) is a preparation of para-amino-benzene sulphonamide. This relatively simple compound has been shown to be a valuable agent in the prevention and cure of infections with haemolytic streptococci. This important chemotherapeutic advance has aroused general interest, and reports on the action of the compound continue to be very favourable. P.B.A.S. is made up in tablets of 0.5 gramme for oral administration. The curative dose recommended is six to nine tablets daily and the prophylactic dose two to six tablets daily.

"ANTOSTAB"

Messrs. Boots have issued a brochure describing the nature and uses of their preparation antostab. This is a preparation of gonadotropic hormones obtained from the serum of pregnant mares. Its activity is standardized biologically by measurement of its action on the ovaries of infantile mice. The preparation is issued in powder form and must be dissolved just before use. This method is necessary because the gonadotropic hormones do not keep well in solution. Antostab is recommended for the treatment of amenorrhoea and of scanty menstruation. Copies of the brochure are available for the medical profession on application to Messrs. Boots Pure Drug Co. Ltd., Station Street, Nottingham.

SYNTHETIC CRYSTALLINE ANEURINE

Benerva brand of Vitamin B_1 (Roche Products Ltd., 51, Bowes Road, N.13) is a preparation of synthetic crystalline aneurine. It is prepared for oral administration in tablets each containing 1 mg. of the vitamin (500 international units). It is also prepared in 1 c.cm. ampoules for parenteral administration. Each ampoule contains 2 mg. (1,000 international units) of the vitamin.

Recent research has indicated that certain forms of neuritis are due to derangements of alimentary functions preventing absorption of vitamin B_1 from the gut. Hence the parenteral administration of this vitamin appears to be an important new form of therapy for certain diseases. Messrs. Roche have prepared useful brochures describing recent clinical results obtained with vitamin B_1.

MILITARY MEDICINE AND PHARMACY

NINTH INTERNATIONAL CONGRESS

A prominent feature of the ninth International Congress of Military Medicine and Pharmacy, held in Bucharest last month, was the general acknowledgement of the practical progress which had been made in reaching agreements designed to reduce the horrors of war as far as possible. Among the 1,400 members of the Congress were official delegates from thirty-one countries and national organizations, and it was decided that the standing committee should be modified so as to comprise representatives of the seven founder countries, together with representatives of the countries which had organized previous international congresses or had applied for membership, and a general secretariat established in Belgium. The modified rules would be submitted to all the Governments concerned, and the executive bureau would come into being in 1938 in connexion with the meeting in that year of the standing committee in the United States of America.

Sectional Proceedings

Six sections of the recent Congress dealt with different topics. In respect of the organization and functioning of the medical services in combined military and naval activities it was decided that attention must be paid both to offensive and defensive operations, and a plan be defined beforehand. Co-operation between the two services should be maintained by the establishment of a single command, the evacuation measures as regards naval vessels being under the protection of the Hague Convention. In all combined military and naval operations there should be a medical base working primarily in conjunction with hospital ships and secondly with depots on land. The unification under a single command of these military and naval depots would facilitate the co-ordination of relief measures on land. Considerable advantages would accrue from the designation of certain towns and maritime centres as depots for receiving the sick and wounded, and a plan has been drawn up providing for these in an international agreement. Another section concerned with gas cases concluded that questions of transport, hospitalization, and treatment were necessarily governed by the nature and the degree of the lesions. Transport presented no special problems, but hospitalization would depend on whether the primary concern was to be surgical or the treatment of gas casualties. Since surgical treatment demanded greater specialization of personnel and equipment, it was agreed that it would be better to establish surgical depots provided with gas sections. If, however, the proportion of gas casualties was very high, the creation of special centres for their treatment would have to be contemplated. The work of detoxication belonged more properly to health services, which would deal both with prophylaxis and with treatment.

A third section reviewed the organization and functioning of the special surgical work required for mechanized units in warfare. These would often be operating independently of the main forces, and the medical services attached to them would have to be endowed with rapidity of movement, be well equipped and provisioned, and capable of functioning independently also. The main purpose of these medical units would be the swift evacuation of the wounded towards the base, because surgical treatment was particularly difficult to arrange for the personnel of quickly moving troops; it would have to be restricted to the most urgent cases, but in unfavourable tactical conditions the work of the medical units would be limited to mass evacuation to special clearing stations. This called for new developments in the organization of evacuation work generally, and the staffs of these quickly moving units would have to be better informed than others so that they might adjust themselves to the rapidly changing needs of very mobile warfare.

The fourth section of the Congress dealt with the employment of colorimetric methods in field laboratories. Dental questions were considered by the fifth section, and it was agreed that partial or complete loss of teeth did not constitute grounds for exemption from military service if dentures proved satisfactory in respect of securing maintenance of the general health and fitness for military duties. The treatment of choice in peace time would be the supply of suitable dentures after the buccal cavity had been rendered healthy by the removal of septic foci of dental origin. In wartime there would have to be facilities for making and repairing dentures in the war zone, for as a general rule there should be no question of evacuating dental cases.

The sixth section dealt with problems relating to the supply of food and the appropriate dietetic treatment of the sick and wounded in wartime. While it was impossible to standardize rations, some scheme of classification was thought advisable, due regard being paid to the economic resources of various countries and especially to national dietetic customs. The feeding of the sick and wounded would necessarily improve as the result of scientific progress, and modern researches in the field of alimentation would play a considerable part in the identification of the more protective foods. In cooking and feeding establishments corresponding benefits would accrue from new discoveries, and gas and electricity would be more extensively used in cooking as well as in cold storage. It might be necessary to establish schools of cookery with a view to limiting the preparation of food to trained and professional chefs. Similarly in hospitals special kitchen departments should be instituted to secure that the dietetic requirements of different classes of the sick and wounded could be met, including the service of the meals in palatable form.

Plenary Session

These various recommendations were embodied in a final recommendation by the Congress as a whole, special emphasis being laid on the importance of securing and safeguarding towns and other centres for medical and health purposes. The advances already made in respect of the various humanizing possibilities pointed to still further progress in the near future, and it was hoped that an international convention would be established to embody all the recommendations envisaged by the various sections of the Congress, humanitarian considerations being accorded primary place henceforth. An invitation by the United States Ambassador to hold the next Congress in Washington in 1939 was unanimously accepted, and thus for the first time the place of meeting would be outside the confines of Europe. General Iliesco would consequently be succeeded as president by Colonel H. W. Jones, leader of the United States delegation. The subjects for discussion then would be: the organization and function of the medical services in colonial warfare (introduced by Italy and the United States); preliminary estimation of the numbers of casualties in war and consideration of the preparation necessary for their treatment (introduced by Germany and the United States); practical methods of anaesthesia and analgesia in military surgery (introduced by Argentina and Czechoslovakia); emergency treatment of and the equipment necessary for maxillary fractures due to war weapons (introduced by France and the United States); and the technical specialization of the administrative officers required for military medicine and surgery (introduced by Mexico and the United States). The exceptional success of the social side of the Congress in Bucarest was gratefuly acknowledged, and keen appreciation was expressed of the services rendered in this respect by King Carol and the Rumanian Government.

The speech by Viscount Astor in the House of Lords on May 5 on the nutrition problem has now been published in a revised form, and includes points made in his reply to the debate. It is particularly commended to social workers, and may be obtained from the National Temperance League, 33, Bedford Place, Russell Square, W.C.1.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY JULY 31 1937

THE BELFAST MEETING

There is a part of Antrim where fairies can be seen by those gifted with unusually good sight, and it is rumoured that several members, well primed with vitamin A to avert night blindness, went in search of them, but unsuccessfully. But these investigators did not allow for a number of factors. Their craving for knowledge was not tempered with scientific caution. A moment's reflection would have informed them that all the fairies in the North of Ireland had been mobilized in Belfast for the Annual Meeting of the British Medical Association. Every Annual Meeting, of course, is a success. If it were not so meetings would not be held annually. A democratic organization such as the British Medical Association is cemented by the unanimity of its members on certain matters of fundamental importance, such as, dare we say, the usefulness of this *Journal*. Among these matters the Annual Meeting is one, and, while not in any way disparaging previous meetings, we agree with the member who remarked that Belfast was an "unqualified" success—by which he meant that he had never enjoyed himself so much before. Irish hospitality and Irish charm made each person feel so much at home that when the time came to leave he parted with regret and "sweet sorrow." The truly Irish qualities of hospitality and charm were epitomized in the President, Professor R. J. Johnstone, whose easy courtesy and unassuming friendliness endeared him to everyone who came into contact with him on private or on public occasions. It was a disappointment to all, and not least to Mrs. Johnstone herself, that illness prevented her from fully enjoying the results of the hard work she had put in as wife of the President. Seldom have the ladies been so well looked after at an Annual Meeting, and many of them will treasure as a memento of the occasion the ladies' handbook bound in Irish linen. It is not possible here to mention by name all those who helped the President to make the Meeting of 1937 the success it was, but special tribute must be paid to the Local General Secretary, Dr. F. M. B. Allen, and his second in command, Dr. R. W. M. Strain. The organization of an Annual Meeting has now become a formidable task, so formidable that the Representative Body considered the question of appointing a whole-time secretary for this purpose. The Belfast Meeting went off without a hitch. So perfectly had the work of organization been carried out, and so complete was the absence of fuss, that few people were aware that the Meeting was being moved by a complex piece of machinery. The grateful thanks of the Association are also due to the civic authorities, who aided and abetted their medical friends at every turn. The Lord Mayor of Belfast, whose reception at the City Hall will long be remembered, worthily maintained the reputation of his city for hospitality.

Although gaiety suffuses the Irish air, however damp this may be, time was, as is customary, set aside for serious matters. Debate at the Annual Representative Meeting was at times not so keen as in former years. Whether the representatives were lulled into quiescence by the genial good nature of the retiring Chairman, Mr. H. S. Souttar, or whether they missed the stimulus of that master of debate, Sir Henry Brackenbury, we do not know. They were at all events meeting in a city not averse to controversy. At an early stage in the proceedings the representatives began seriously to consider whether they were really representative or not, and discussed at great length a proposal that a general practitioners committee be formed, whose "duties and powers would be to consider matters specially affecting general practitioners." Those who spoke in favour of the motion were pleasantly oblivious of the humour of the situation. After all, the great majority of the members of the Association are in general practice, and the B.M.A. consists of its members—it does not exist *in vacuo*. The proportion of general practitioners is also well maintained in the Representative Body, which determines by vote the policy of the Association. What could be more representative than this? The fundamental error is in looking upon the interests of one section of the profession as distinct from and opposed to those of another. The B.M.A. must, and indeed does, concern itself with the interests and activities of all branches of medical practice, for medicine is one profession, not many. Of greater relevance was the discussion on maternity services, and readers of the *Journal* will endorse the resolution "that the Representative Body views with growing anxiety the tendency to divert from the general practitioner the practice of midwifery

and its associated ante-natal work." There was no doubt that that wise medical statesman Sir Kaye Le Fleming had well weighed his words when he described the difficulty as "the taking of a purely medical question into the political arena until the politician was driven to do something for political reasons, and . . . the absence of a proper means of approach by the local medical profession to the local authority."

Strangely enough few people found themselves able to agree with the *Times* leader writer, who on Tuesday, July 20, described the Belfast programme as "old-fashioned, musty, even threadbare." As the Scientific Sections did not begin until Wednesday, July 21, no one, however omniscient, could have foretold the nature of the discussions on subjects of which he may or may not have had expert knowledge. And the value of the Scientific Sections lies chiefly in the free discussions that take place on subjects which, old and new, are relevant to the daily practice of medicine. To the visionary, no doubt, such matters as "individual variations in response to drugs," "tomography," "protamine insulin," "the use of vitamin E in habitual abortion," are all threadbare and even musty subjects. Nevertheless unusual interest was shown in these and other matters on the scientific programme, and the level of discussion was considered to be unusually high. The report of the British Medical Association Committee on Physical Education—the basis of much public discussion and activity since its publication in April, 1936—might have been circulated to those attending the Section meetings to remind them of what they already knew: in the maintenance of health many factors enter, of which physical activity is but one. Those who arranged the scientific programme were also well aware that a body that is ill fed needs rest and nourishment and not the "physical action" lauded in the *Times* leading article. The medical profession is rightly less concerned with "the glamour of action beyond the normal level" than with seeing that the normal level is maintained: proper nutrition, good working conditions, adequate housing, and recreation are necessary for this. When these have been obtained, then will be the time for studying "the glamour of action."

We cannot conclude this brief review of the Belfast Meeting without reference to the enthusiastic reception given to Major-General William MacArthur's popular lecture on "Insects and Disease." The meeting ended as it began, in a spirit of real friendliness and comradeship. Those who had visited Ulster for the first time left with the firm resolve to return at the earliest opportunity —an opportunity which is not to be missed.

SPINAL TUMOURS: A JUBILEE

There are few surgical experiences more satisfying than that of seeing a paralysed, bed-ridden, and incontinent patient restored to health and normal life as a result of the diagnosis, localization, and successful removal of a spinal tumour. Just over fifty years ago it was Sir Victor Horsley's privilege to be the first to have this gratifying experience, and to some the event is more memorable even than Sir Rickman Godlee's operation for a cerebral glioma, of which the half-centenary was celebrated three years ago by a dinner and appropriate references to the occasion on the part of some of the chief guests. Although brain tumours are six times as common as spinal cord tumours, the latter are just as remorseless if not prevented from producing a steadily progressive destruction of the cord by compression. It is well known that once complete destruction of a section of the human spinal cord has taken place it does not regenerate. The recognition and removal of spinal tumours before such destruction of the cord has come about is therefore of the utmost importance. It is surprising, however, to what an extent the cord may be compressed by a tumour and yet recover its function after operation. We have now almost daily evidence of this in the successful recovery from paraplegia of patients with spinal tumour, in many of whom at the time of operation the cord has been found to be extensively compressed.[1]

On the afternoon of June 9, 1887, at the National Hospital, Queen Square, Victor Horsley performed laminectomy on an Army officer, aged 42, who had suffered from severe pain below the inferior angle of the left scapula for three years and who had spastic paraplegia in extension. Sir William Gowers, in whose care the patient had been, diagnosed a spinal tumour and advised operation, and in this Sir William Jenner, who also saw the patient, had concurred. Throughout the operation the carbolic spray was used and instruments and sponges were immersed in 5 per cent. carbolic lotion. No tumour was found, and the operation was about to be concluded when the late Sir Charles Ballance,[2] who was assisting, urged Horsley to go higher. In his report of the case Horsley[3] remarks: "I removed another lamina at the upper part of the incision. On opening the dura mater I saw on the left side of the subdural cavity a round, dark, bluish mass about three millimetres in diameter, resting upon the left lateral column and posterior root zone of the spinal cord. I recognized it at once to be the lower end of a new growth and therefore quickly cut away the major part

[3] *Med. chir. Trans.*, 1888, 71, 377.

of the lamina next above. This enabled me to see almost the whole extent of the tumour when the dura was divided." This tumour, the first ever to be diagnosed and successfully removed from the living subject, is specimen 5063–1 in the Hunterian Museum of the Royal College of Surgeons of England. It is interesting to note that although the cord was swabbed with 5 per cent. phenol and the patient had a cerebro-spinal fluid fistula for six weeks he made an astonishingly complete recovery, and a year after the operation wrote to Horsley that he was in excellent health and working sixteen hours a day. Horsley was so far ahead of his time that ten years elapsed before an equally successful result was obtained in a case of Harvey Cushing's,[1] not reported until 1904.

The case operated upon at Queen Square fifty years ago marks a great original effort, and in thinking of those pioneers in the surgery of the spinal cord we are reminded of the lines from Coleridge's *Ancient Mariner*: "We were the first that ever burst into that silent sea." Only six years before Horsley's highly successful operation Herbert Page of Newcastle-on-Tyne had described laminectomy as "an operation not within the range of practical surgery," and when Horsley published this case he collected records of fifty-eight other patients untreated by operation, all of whom had died. It is fitting that we should be honouring, at least by reference to it, the half-centenary of Horsley's spinal tumour case, for as the late Donald Armour once said (Lettsomian Lectures, 1927), this epoch-making occasion proved to be the birth of spinal tumour surgery.

THE PATHOLOGICAL MUSEUM AT BELFAST

It may safely be said that no more instructive collection of pathological material has been exhibited at an Annual Meeting of the British Medical Association than that shown at Belfast. The greater part of it consisted of specimens which have been collected for teaching purposes under the direction of Professor Young during the past few years. The material was admirably chosen either to illustrate typical disease processes or to exemplify unusual abnormalities. Not only were the specimens themselves well mounted and displayed, but the presentation of clinical data connected with them was admirable, and frequently included reproductions of skiagrams taken during life and other such illustrations of the case other than the specimen itself. The more closely the pathological process can be related to clinical symptoms and signs the better will it be understood by the student and the greater his gain from pathological teaching. An unusual feature was the demonstration on viewing screens of large histological sections: one group of these was devoted to breast tumours, in which it was instructive to be able to see at a glance the situation and extent of a growth and the direction of its spread. On another were a variety of similar specimens, including several sections through the entire uterus in cancer at various stages; these beautiful preparations afforded a picture of what may be called the anatomy of a disease which is quite unattainable by other means. Perhaps the most striking specimens in the general collection were those illustrating malignant disease of the lung, of which many types were represented; there was also a varied series of tumours of the brain. Several special exhibits were devoted to tumours of bone, a subject which was discussed by the combined Sections of Pathology and Radiology on July 22; many of the specimens shown were from cases referred to by speakers at that meeting. Professor M. J. Stewart exhibited specimens illustrating the fact that giant-celled tumours of bone include a type which may metastasize, and examples of the solitary plasmocytoma, a tumour which may present considerable difficulty in diagnosis and is, indeed, still imperfectly recognized. Examples of plasma cell tumours were also shown by Professor D. F. Cappell and Dr. L. M. Hawksley. Among other exhibits were a demonstration by Sir Thomas Houston on types of enterococci, by Dr. Eileen Bartley and Dr. N. C. Graham on the cultural disturbances between Lancefield's groups of haemolytic streptococci, and by Professor C. C. Macklin on experimental pneumothorax. It should be added that in connexion with the morbid anatomical exhibits histological sections of every specimen were provided, together with plenty of microscopes by which they could be examined. Many visitors must have felt that had the programme of the meeting not been so full they could profitably have spent a much longer time than they did in studying this excellent collection.

A NEW TREATMENT FOR DIABETIC KETOSIS

Professor Szent-Györgyi has just given an account of a new treatment for diabetic ketosis, producing evidence that the administration of succinic (amber) acid by mouth quickly removes acetone bodies from the urine. Rumours of this treatment had appeared in the British lay press even before his scientific publication[1] in Germany. The idea is revolutionary, and coming from such a source commands serious attention. It is suggested that injections of insulin may be replaced by succinic acid by mouth in the treatment of patients even with severe ketosis. Szent-Györgyi's idea is based on the theory he has previously advanced, which is by no means generally accepted, of the vital part played by C_4 dicarboxylic acids, especially pyruvic acid, in tissue respiration and intermediate carbohydrate metabolism. This led him to think that the C_4 succinic acid might help as a catalyst in the disordered metabolism of diabetes, particularly the ketone disturbance. Five cases of diabetic ketosis have been treated by succinic

[1] Korányi, A., and v. Szent-Györgyi, A. (1937). *Dtschr. med. Wschr.*, 63, 1029.

acid, and according to the published account successful results were obtained in four of them. The first case is the most striking. After the omission of 70 units of insulin a day the administration of 10 grammes of succinic acid by mouth completely removed a heavy urinary ketosis in four days, although the hyperglycaemia and glycosuria remained unchanged. The succinic acid was then stopped, and the ketosis recurred, to disappear again two days after restarting the acid. This procedure of omitting and restarting the treatment was repeated, with the same result, and the patient was ultimately controlled with 1 gramme of succinic acid and 10 units of insulin daily. The results lead the authors to suggest that injections of insulin may be replaced by succinic acid by mouth, a matter of enormous importance to thousands of patients with diabetes. In the current issue of the *Journal* Dr. R. D. Lawrence and his colleagues publish on page 214 a short report of their preliminary trial of the succinic acid treatment, describing entirely different and negative results. Two women with heavy ketosis were given 10 grammes of succinic acid for a week, during which time the ketosis grew steadily worse, to disappear rapidly later under insulin treatment. These workers are satisfied that the experimental conditions were well controlled, and their results are definite. There is, therefore, a complete contradiction in the results of two groups of workers, neither of whom have studied many cases. It is clear that many more cases must be followed under strictly controlled conditions and by other observers, and the changes in ketosis must be studied by qualitative estimations as well as by qualitative tests. It may be that succinic acid acts in some but not in all cases of diabetic ketosis, as it seems likely that there is more than one type of diabetes. At all events it is too soon to advise the general use of succinic acid in place of insulin; from Dr. Lawrence's experience it is evident that this would in certain cases involve the risk of diabetic coma.

"JOURNAL OF NEUROLOGY AND PSYCHIATRY"

Since 1926 the *Journal of Neurology and Psychopathology* has been issued four times a year by the British Medical Association, and the 68th number appeared in April, 1937. The contents have included original communications and editorial articles, together with abstracts of current neuro-psychiatric literature and critical reviews. Until his much-regretted death on May 12 Dr. S. A. Kinnier Wilson, with the assistance of an Editorial Committee, edited the journal, and under his guidance it established itself as one of the foremost periodicals for the record of progress in the branches of medicine with which it deals, its scope and arrangement giving it a place which no other journal published in English exactly copies. The position created by Dr. Wilson's death was fully considered by the Editorial Committee and the following decisions were made. No further issues will be published this year. The next, No. 69, will appear in January, 1938, under the editorship of Dr. E. A. Carmichael, with its title changed to *Journal of Neurology and Psychiatry*. The accounts of subscribers will be adjusted to make up for the temporary suspension of publication. All communications on editorial matters should be addressed to Dr. Carmichael, National Hospital, Queen Square, London, W.C.1, and on business matters, to the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1. Under the new printing arrangements the size of page will be larger. The cost is 25s. per annum (20s. to members of the British Medical Association); single numbers 7s. 6d. post free.

FOOD-POISONING DUE TO MILK

At this time of year there commonly arise cases of acute enteritis for which a cause can rarely be found. Living bacteria of the Salmonella group are readily identified, but they account for only a small proportion of food-poisoning outbreaks, and when their presence has been excluded the remaining possibilities are less amenable to investigation, and indeed usually remain in the field of conjecture. That the multiplication in food of other less specific bacteria may have similar effects is undoubted, although to attribute a given case to the activities of a particular micro-organism may be a matter of great difficulty. Within the past few years, however, another specific type of food-poisoning has been identified among these miscellaneous cases. This type is due to the formation of a toxin in food by the growth of *Staphylococcus aureus*; it may be suspected when the incriminated food contains this micro-organism in considerable numbers, but proof is only obtainable by the administration of culture filtrates to human volunteers. It is still doubtful whether any character other than the capacity to form this enterotoxin can be used to distinguish the true food-poisoning strains of staphylococci. Simpler cultural tests have been proposed, but it now appears that the administration of filtrates to monkeys, which was at first thought to be a satisfactory test for staphylococcus enterotoxin, is not reliable enough. It may be remarked in passing that this is the only fully identified exotoxin with a local action on the alimentary tract, just as the toxin of *Cl. botulinum* is the only toxin which can be absorbed there. The literature of this form of food-poisoning is almost entirely transatlantic, and it is not clear whether the condition is actually commoner in America or whether its existence in this country, for instance, is still largely unrecognized. Although a variety of articles of food have been known to cause this form of food-poisoning, milk, milk products such as custard, and confectionery containing cream have most often been responsible. Shaughnessy and Grubb[1] have recently described the investigation of outbreaks due to milk itself, and it was found in each case that the herds supplying the milk included cows with staphylococcal mastitis. This is important evidence pointing to a distinct origin of this type of contamination, and suggesting that only certain strains which are pathogenic to the cow can be responsible; staphylococci, after all, are so ubiquitous that any chance contamination cannot be deemed capable of causing this form of food-poisoning. Brooks and Tiedeman,[2] in a general discussion of the relation of

[1] *Canad. publ. Hlth. J.*, 1937, 28, 229.
[2] *Amer. J. publ. Hlth.*, 1937, 27, 334.

bovine mastitis to human disease, also refer to staphylococcal infection of the udder as a cause of gastro-enteritis in man. This is clearly a possibility which should be borne in mind in investigating outbreaks of food-poisoning, even though the ultimate proof of their staphylococcal origin may present insuperable difficulties until some more convenient test for this entero-toxin has been devised. These discoveries throw an interesting retrospective light on the summer diarrhoea of infants. It has long been suspected that various bacteria, other than the recognized intestinal pathogens, by multiplying in milk can produce substances which will act as irritants in the alimentary tract. Here is the fullest possible proof that a micro-organism, the presence of which would otherwise be disregarded, can form a toxin which will cause vomiting, diarrhoea, and collapse even in the adult. How many of the multitudes of infants who used to die of gastro-enteritis were suffering from food-poisoning due to staphylococci, or perhaps other bacteria acting similarly, will never be known. There is every reason for supposing that pasteurization and fewer house-flies have been responsible for the enormous reduction in frequency of this disease. In such cases as do occur nowadays a series of examinations of the milk consumed, with particular reference to its coccal content, might have illuminating results.

LE DROIT DES SAVANTS

On June 8 one more step was taken in the direction of giving scientists material rewards for their discoveries when the French Academy of Medicine passed a resolution in favour of this principle. During the past decade this problem has appeared from time to time on the agenda of scientific and allied bodies, including the League of Nations and its offspring the International Institute of Intellectual Co-operation. In a report presented on behalf of the Commission of Intellectual Co-operation, Bergson maintained that in the scientific field a new idea, not only its application, deserved protection on behalf of its author. Last March a study of the rights of savants was presented to the Academy of Medicine by Paul Olagnier. The commission, which was appointed by the Academy, and which was composed of some of its most distinguished members, has now issued its report, and it was as a response to this report that the Academy on June 8 unanimously voted a resolution in which the Government was invited to submit to Parliament the draft of a law aiming at the preservation of the rights, moral and material, of savants and inventors in all the fields in which their discoveries and scientific inventions exist. In the preamble to this resolution it was noted that legislature as it now stands does not grant to savants the same rights with regard to their discoveries and inventions as those enjoyed by the authors of literary and artistic works. It has seemed for some time that the discussion of this subject by learned societies has inevitably been doomed to the futility of pious wishes lacking executive expression; but what has given rise to hopes that this problem may be transferred from the academic to the legislative plane is that the French Government has prepared the draft of a law amplifying and harmonizing already existing legislation concerning authors' rights. With good will it ought not to be difficult to couple these proposed reforms with clauses extending the rights of authors to scientists in Bergson's spirit.

LESTER INSTITUTE, SHANGHAI

The annual report for 1936 of the Henry Lester Institute of Medical Research, Shanghai, is as interesting as its predecessor. This institution is notable for the close liaison it facilitates between its workers and centres of research in Europe, and for the catholic range of its local activities and their practical application. Further field investigations have been conducted with regard to schistosomiasis. During the summer months a party of some sixty Russian boy scouts were encamped in the hills twenty miles south-west of Shanghai, and on their return to the city many of the boys were found to be infected with the disease. The Institute immediately despatched investigators to the district, where numbers of infected snails were discovered. Monthly visits were initiated to study the bionomics of *Oncomelania*, an essential prelude to the control of the disease in an endemic area. The report stresses the danger of bathing in creeks or ponds within a hundred miles of Shanghai. A considerable incidence of infection with *S. japonicum* was found in the cattle slaughtered in the municipal abattoirs. The livers of 156 oxen and 140 water buffaloes were examined for the ova, in one series of oxen 33 per cent. were infected and 23 per cent. in a series of water buffaloes. The study indicates that cattle may serve as an important reservoir host of schistosomiasis in China, although it is pointed out that transmission cannot be direct, the snails constituting a necessary intermediate host for the development of the Cercariae. The report records the retirement of Dr. J. L. Maxwell, one of the founders of the Institute, and interesting extracts are quoted from his valedictory lecture. When Dr. Maxwell went to China thirty-six years ago typhoid cases, which at that time still laid a heavy burden on the medical wards of St. Bartholomew's, were very infrequent among the Chinese in Amoy, then reputed one of the dirtiest cities in China. Amoy is now one of the finest cities of the Far East, with an unrivalled supply of pure water. Nevertheless, typhoid is to-day one of the main causes of Chinese admissions to its hospitals, and takes the leading place in the mortality rate. In short, the disease has enormously increased in circumstances which would have been expected to produce the opposite effect. Dr. Maxwell also mentions the great increase in neurosyphilis. He attributes the spread of syphilis in country districts to the ubiquitous wanderings of a licentious soldiery during the last twenty-five years, and infers that the unaccustomed nerve strain engendered by wholesale brigandage has concentrated the ravages of the disease on the central nervous system. With regard to the future of medical research in China, Dr. Maxwell stresses the need for team work. He also points out that, though increasing attention is paid to physical health, especially with regard to nutrition, the question of mental health and also of spiritual health is comparatively neglected.

ANAESTHESIA IN GENERAL PRACTICE

This is one of a series of articles, contributed by invitation

NOTES ON THE PHYSIOLOGY AND PHARMACOLOGY OF ANAESTHESIA

BY

H. W. FEATHERSTONE, M.A., M.D., D.A.

General surgical anaesthesia may be defined as the state of profound insensibility produced by the action of certain drugs on nerve cells of the brain without harming the essential processes of respiration and circulation, and sufficiently profound to allow a surgical operation to be performed. Local anaesthesia comprises loss of sensation over an area caused by a drug acting directly on nervous tissue to which it has been applied. It is the purpose of this article to discuss from a practical point of view the various routes by which these drugs enter the body, the effects they produce, and their ultimate fate.

General anaesthetics are administered in the gaseous or in the liquid state. Solid drugs are given in solution.

Volatile Anaesthetics

Gaseous anaesthetics which enter the body through the lungs are called inhalational anaesthetics. This group includes nitrous oxide, ethylene, acetylene, and cyclopropane, and the vapours of di-ethyl ether, divinyl ether, chloroform, and ethyl chloride. Since an inhalational anaesthetic is speedily absorbed and excreted by the blood through the alveolar epithelium the drug may be given with safety in full pharmacological dose to the point of deep surgical anaesthesia, and provided respiration and circulation are maintained reduction in dosage can be effected readily. On the other hand the dose of non-volatile anaesthetics cannot be reduced rapidly, and therefore deep anaesthesia is not compatible with safety. If a volatile anaesthetic such as ether is administered in solution either intravenously or by the rectum the drug will be excreted by the lungs.

In the upper air passages certain direct effects may be produced: irritation of the mucous membrane accompanied by vasodilatation, secretion of mucus, muscular spasm; after some minutes these signs of irritation may be followed by local anaesthesia of the walls of the air passages and by muscular relaxation. Ether (in the absence of atropine) is especially prone to cause these events, but chloroform and ethyl chloride are less irritating and nitrous oxide and ethylene are non-irritating.

ABSORPTION AND ELIMINATION

The direction of the diffusion of the vapour through the alveolar epithelium depends upon the partial pressure in the alveoli and the tension in the blood. So long as the partial pressure of the vapour in the air cells is higher than its tension in the blood the drug is absorbed by the blood. Although the alveolar epithelium does not appear to suffer damage during anaesthesia of normal duration, high concentrations of ether or of chloroform acting over a long period may cause more or less permanent injury to these cells. Deep inspiration draws a larger volume of gas into the lungs, and at the same time the increased power of the thoracic "pump" promotes a more rapid flow of blood through the heart and lungs. Therefore by full respiratory movements absorption of anaesthetic gases is increased; or after the administration has ceased excretion of the drug is encouraged.

In the blood the drug is carried partly in solution in the plasma and partly in the red corpuscles, either in a loose chemical combination or by adsorption. After passing through the left heart the anaesthetic-laden blood is propelled to the brain and to the tissues of the body. It is common experience that for a particular anaesthetic the longer the duration of administration the more the delay in recovering consciousness. Brief administration produces a certain tension of the gas in the blood, but the lymph and the body tissues generally do not have sufficient time to store up the drug. On the other hand prolonged anaesthesia causes the anaesthetic to accumulate in all the tissues, although it is necessary to prolong administration for several hours before the concentration in the arterial blood, the venous blood, and the tissues is in equilibrium.

McKesson introduced the method of administering nitrous oxide and oxygen, which he termed "secondary saturation." One hundred per cent. of nitrous oxide is inhaled until the patient is grey, and therefore the blood contains a maximum tension of nitrous oxide, which ensures that the tissues in general and the nerve cells in particular rapidly obtain a maximum concentration of the drug. Oxygen is then driven into the lungs (and into the blood), and thereafter a mixture of nitrous oxide and oxygen in the usual proportions is administered. The period of greyness and anoxaemia which accompanies the saturation with nitrous oxide is considered by many anaesthetists to endanger the safety of the heart muscle.

When the administration is stopped elimination proceeds rapidly at first, particularly if the circulatory and respiratory functions are vigorous, and then more gradually. The last traces of the less volatile drugs may be retained for several days. The bulk of an inhalational anaesthetic drug is excreted through the lungs, a detectable amount through the skin, and possibly traces of ether and chloroform are oxidized by the liver and the products excreted by the kidneys.

EFFECT ON THE BLOOD AND THE NERVOUS SYSTEM

All types of general and local anaesthesia produce a leucocytosis, and among other changes in the blood which have been recorded the following may be mentioned: reduction in the amount of haemoglobin, anaemia, haemolysis, prolongation of the coagulation time, increase in the blood cholesterol, reduction of the oxygen content, and an increased percentage of carbon dioxide. These effects are rare with nitrous-oxide-oxygen anaesthesia, but they have been noted with ether and with chloroform. The alkali reserve of the blood is reduced and some degree of ketosis occurs. The glycogen of the liver is mobilized and the blood sugar rises. Undoubtedly these effects are increased by cyanosis, by prolonged anaesthesia, and particularly by chloroform. The administration, before and after operations, of sodium bicarbonate and of glucose (together with insulin, especially in diabetics) is of much service, good oxygenation is essential, and nitrous oxide and oxygen is the least disturbing (but the weakest) anaesthetic agent.

Anaesthetic drugs are not only readily taken up by the blood but nerve cells have a special affinity for them.

The cells in the higher centres of the cerebral hemispheres are affected first, and the centres for the sensory cranial nerves subsequently—smell, then vision, then hearing. Probably oxidation of the nerve cells, upon which the function of the cells depends, is affected by the drug by interference with the selective permeability of the surface membrane of the cells. If the higher centres are very active at the time of induction a higher concentration may be required to inhibit function. This is the rationale of careful pre-operative sedation, either by natural means or by drugs. An individual in a state of mental excitement may require such a large concentration to control the nerve cells of the higher centres that the function of the lower centres may be affected as well. Anaesthetic agents do not affect the various portions of the cerebrum in quite the same order. Thus chloroform and nitrous oxide usually produce analgesia before confusion of the mind and amnesia set in, but ether confuses the mind at the same time as it abolishes pain.

The concentration of a drug in the blood which is necessary to inhibit the activity of a particular group of nerve cells varies with different drugs. At normal atmospheric pressure the greatest partial pressure of nitrous oxide which permits adequate oxygenation will not produce muscular relaxation. In a pressure chamber, working at a pressure of one and a half atmospheres, nitrous oxide becomes more potent. But ethylene is rather more powerful than nitrous oxide, while ether or chloroform will cause muscular relaxation with adequate oxygenation and unimpaired respiratory and circulatory functions.

TOXIC EFFECTS

In the presence of an adequate oxygen supply nitrous oxide, ethylene, and cyclopropane do not impair liver function; but liver function may be diminished by ether for some hours and by chloroform for days. Permanent degeneration, sometimes fatal, occurs in the condition known as delayed chloroform poisoning. The late Dr. Fairlie of Glasgow, with his great experience of chloroform, considered that minor degrees of damage to the liver were not uncommon. Pre-operative loading of the liver with glycogen is a safeguard, and for this purpose glucose or sodium lactate (the liver converts lactic acid into glycogen) may be given for several days before operation.

Anaesthetics affect the heart by poisoning the neuromuscular mechanism and by causing vagal inhibition. In the early stages of chloroform anaesthesia ventricular fibrillation may follow excitement or the injection of adrenaline. Anoxaemia may lead to failure of the heart muscle itself, and this danger may be caused either by complete displacement of the oxygen (for example, by giving 100 per cent. nitrous oxygen in "dental gas" anaesthesia) or by obstruction to the air intake. Inefficient heart action delays induction and recovery. This is clearly demonstrated when giving gas and oxygen to patients with morbus cordis.

Vasomotor control is usually disturbed by the direct action of the anaesthetic upon the vasomotor centre in the medulla. Thus if the head and shoulders are raised compensatory vasoconstriction of the lower parts of the body will not occur and cerebral anaemia may follow. But lowering of the head, as in the Trendelenburg position, is safe and salutary. Nitrous oxide produces slight vasodilatation, and the blood-pressure readings in the absence of shock in ether and in chloroform anaesthesia are instructive. With ether an initial rise in the systolic pressure is followed by a gradual fall, while the diastolic pressure falls steeply at first and remains low until the anaesthetic is stopped, when it usually rises rapidly. Thus the pulse pressure under ether is large, the heart has less work against a lowered peripheral resistance, but cut surfaces tend to bleed more freely. Chloroform anaesthesia is accompanied by a slow fall in the systolic pressure and a rise in the diastolic reading. Therefore the pulse pressure diminishes, the heart works against an increased peripheral resistance, but there is a tendency for the bleeding of cut surfaces to be lessened. It is said that etherized patients bleed at the time of operation, but those who have had chloroform bleed after the operation!

The heat centre is also depressed, and as the metabolism of the body is reduced during anaesthesia the lowering of the body heat may be considerable. Adequate covering of the body, the avoidance of draughts, and a well-warmed theatre are called for.

The function of the kidneys is not demonstrably affected by nitrous oxide and oxygen anaesthesia, but ether and particularly chloroform tend to produce oliguria and anuria. Albumin may be detected in the urine after ether and sometimes after chloroform. Acetonuria was present in 67 per cent. of a series of patients upon whom any one of the various forms of general anaesthesia had been used, and "in no less than 85 per cent. under local analgesia" (Schulze, quoted by Hewer). The blood urea shows a slight rise after ether anaesthesia.

Bourne and Burn have demonstrated that the contractile power of the uterus in labour is inhibited by ether and by chloroform. Nitrous oxide and air or nitrous oxide and oxygen permit uterine activity to continue with normal rhythm and contractile power. Spinal analgesia appears to promote tonic contraction of the circular muscle, but the longitudinal fibres do not function effectively

Non-volatile Anaesthetics

Among those in common use may be mentioned avertin (tribromethylalcohol) and the rapidly acting barbiturates such as evipan sodium, pentothal sodium (which contains sulphur), pernocton (which contains bromine), sodium amytal, and nembutal. These preparations are all soluble in water, and they are administered by the mouth, by the rectum, by intramuscular injection, or by injection into a vein; but all are not suitable for administration by all routes. Avertin is always administered rectally; evipan sodium and pentothal sodium if injected into the tissues cause severe local reaction, and they are *par excellence* intravenous anaesthetics. If nembutal, the soluble sodium salt of an insoluble barbiturate, is swallowed by a nervous patient the drug may be retained for some time in the stomach by functional pyloric spasm, with the result that the gastric hydrochloric acid may cause precipitation of the insoluble compound and the absorption of the drug may be delayed. Nevertheless nembutal is a useful oral basal anaesthetic.

Each of these substances is detoxicated by the liver, and the oxidized products, together with salts derived from the bromine or sulphur components, are excreted by the kidneys.

The barbiturates not only vary in the particular nerve cells for which they have affinity (luminal has a markedly sedative action in conditions of motor hyperexcitability, such as chorea), but they vary in the rate of detoxication and elimination, sodium amytal being slowly detoxicated, while evipan sodium and pentothal sodium are eliminated with great rapidity. If the property of speedy detoxication is accompanied by a wide margin of safety—that is, if the minimal lethal dose is three or four times the narcotic dose—then the drug may be given into a vein

in sufficient quantity to produce complete narcosis and muscular relaxation. The guide to the dose is the reaction of the patient. Slow administration by other routes—oral, rectal, or intramuscular—is employed for the slowly detoxicated barbiturates and for avertin. The dose is calculated according to the weight of the patient, and unconsciousness only is aimed at, the further depth of anaesthesia being attained by administering a relatively low concentration of an inhalational anaesthetic.

Respiration and the General Circulation

After an operation of average length under either general or spinal anaesthesia there may be marked pallor of the face and body. The prolonged immobility of the body, together with complete muscular relaxation, has reduced the circulation considerably. Deficiency of carbon dioxide (Yandell Henderson) and the reduced metabolism have also tended to produce this appearance.

The administration of carbon dioxide stimulates the respiratory centre and the movements of respiration are increased both in rate and in amplitude. Not only does this improve the colour of the patient by increased ventilation but the return of blood to the heart is also accelerated. On the other hand excess of carbon dioxide may depress the heart muscle. The accumulation of carbon dioxide and other waste products in the muscles tends to cause muscular rigidity.

The administration of oxygen improves the heart's action and helps the functions of other important organs; furthermore, it relieves congestion in the blood vessels of the air passages. Cyanosis after nitrous oxide may lead to vomiting and malaise, but a few breaths of oxygen speedily restore the sensation of well-being. It should be remembered, however, that the pink colour associated with breathing a mixture rich in oxygen may mask defective exhalation of carbon dioxide should the upper air passages or the return flow from an intratracheal catheter be partly obstructed. It is as important to free the body of the waste product carbon dioxide as it is to provide an adequate supply of oxygen. Therefore under general anaesthesia a proper airway is at all times essential.

Local Anaesthetics

These drugs paralyse nerves and nerve endings in concentrations at which they do not injure surrounding tissues and without preliminary excitation. The duration of action is temporary, but more than half an hour (quinine-urea lasts longer and tends to leave permanent effects). They are soluble in water but not destroyed by boiling; they may be combined with adrenaline, and they do not exert a markedly toxic central action. They may be applied by painting on to surfaces; by percutaneous electrolysis; by injection, either hypodermically to paralyse nerve endings or subdurally to paralyse the spinal cord and the spinal nerve roots. These drugs vary in their toxic power upon the brain and other organs, cocaine being potent and novocain relatively innocuous. Adrenaline is injected along with the drug in order that local vasoconstriction and local concentration of the drug may be secured. A large bulk of highly dilute solution increases the tension in the tissues, and thereby pressure paralysis of the nerve fibres is caused.

Patients may suffer discomfort following local anaesthesia. The adrenaline may cause palpitation, pallor, and even alarming derangement of the heart's action. There may be marked idiosyncrasy to the local anaesthetic, and often this effect is not shown immediately but during the few hours subsequent to the injection when, the local vasoconstriction having relaxed, the drug is being dispersed into the circulation. Novocain is rapidly detoxicated by the liver and the products are excreted by the kidneys, but cocaine is detoxicated slowly and excreted slowly.

Spinal Analgesia

By the direct application to the spinal cord of local anaesthetic drugs (tropacocaine, stovaine, novocain, percaine, etc.) the passage of both afferent and efferent impulses along the spinal roots may be blocked, the sensory roots being affected more easily. A solution may tend to diffuse up or down the intrathecal space, and dorsally or ventrally as it is heavier, lighter, or of the same specific gravity as cerebro-spinal fluid—that is, hyperbaric, hypobaric, or isobaric—and as the body is prone, supine, upright, or inverted head downwards. The duration of the analgesia is usually from one to two and a half hours, and the drug is ultimately excreted by the same route as other local anaesthetics.

Not only are the motor and sensory actions of the affected nerve trunks and tracts abolished, but should the thoracic region of the spinal cord be affected extensive vasomotor paralysis ensues. The fall in blood pressure may be considerable. It has been suggested that this fall is due to relaxation of the trunk and lower limb muscles, accompanied by stagnation of blood in the capillaries and veins and increased exudation of lymph. In this way the paralysed region of the body becomes a lake of lymph, while the bulk of blood available for return to the heart is greatly reduced. Should the head be raised and the legs lowered cerebral anaemia may produce syncope. In elderly persons the arterial peripheral resistance may be relatively high. According to the formula $S = 2D - 20$ (systolic should be equal to twice the diastolic pressure minus 20 mm. Hg) a diastolic pressure of 120 mm. Hg requires a systolic pressure of 220 mm., but if a pre-operative diastolic reading of 120 mm. were accompanied by a systolic pressure of only 180 mm. a spinal anaesthetic might cause such lowering of the systolic pressure that serious cerebral anaemia might result.

Headache after spinal analgesia may be severe. It may start a few hours after the administration or the headache may not occur for a week. Usually occipital or sub-occipital, it may be exaggerated by raising the head. The intrathecal pressure is raised and the headache is always relieved, temporarily at least, by lumbar puncture. The headache may follow simple diagnostic lumbar puncture, and although injection of air bubbles, intrathecal bleeding, direct effects of the drug, and other possible causes have been deemed responsible, it is probable that the condition is due to the sudden disturbance of the intrathecal pressure associated with lumbar puncture, with or without the injection of a drug. The application of heat to the feet with ice to the head, accompanied by a saline aperient and a mild analgesic, usually relieves the condition.

When spinal anaesthetics are combined with powerful basal anaesthetics whose elimination depends upon detoxication by the liver undesirable effects may result. The drop in blood pressure is more marked than usual, the respiration often is slowed and reduced in depth. The depression of circulation retards detoxication, and until the effect of the spinal anaesthetic has worn off basal anaesthesia will persist. Stimulation of the respiration and of the circulation by means of inhalations of carbon dioxide and oxygen hastens detoxication and helps to break the vicious circle.

ONE HUNDRED AND FIFTH ANNUAL MEETING

of the

British Medical Association

HELD IN BELFAST, JULY, 1937

THE SECTIONS

SUMMARY OF PROCEEDINGS

During the next few months there will be published in the BRITISH MEDICAL JOURNAL *the opening papers communicated to the Scientific Sections of the Annual Meeting at Belfast. The reports of discussions in this and successive issues are intended to give members who were not present a general idea of the proceedings.*

COMBINED MEETING OF SECTIONS OF MEDICINE AND PATHOLOGY

Wednesday, July 21

The Haemorrhagic States

The president of the Section of Medicine, Professor W. W. D. THOMSON, welcomed members to Belfast, and asked Sir THOMAS HOUSTON, president of the Section of Pathology, Bacteriology, and Immunology, to take the chair.

Professor L. J. WITTS delivered the opening paper on the haemorrhagic states. He said that these conditions did not lend themselves to rigid classification, since the factors causing haemorrhage were complex, but it was convenient to divide them into those in which the blood failed to clot normally and those in which the bleeding time was prolonged. Hereditary haemorrhagic states showed a diversity in their mode of inheritance which had not always been appreciated. In the treatment of haemophilia the local application of coagulant venoms was an important advance, but liver extract, oestrin, and moccasin venom had been failures, and he himself had obtained no results from the Sheffield extract of egg albumen. Idiopathic thrombocytopenic purpura was now a well-defined condition, and splenectomy was the most successful treatment for it, but its *modus operandi* was imperfectly understood and relapse was frequent. Vitamin C was a remedy which had been tried in a variety of haemorrhagic states, but it was of value in scurvy only. The discovery of ascorbic acid had nevertheless been a stimulus leading to further research, and the newly identified vitamins P, K, and T awaited clinical trial. It was important that such trials should be thoroughly carried out on chronic cases, which were more suitable for experiment than acute cases, and that objective criteria obtained by quantitative tests should be used in assessing the value of such remedies.

Dr. N. B. CAPON (Liverpool), discussing haemorrhagic conditions in the newborn, pointed out that spontaneous haemorrhage might occur in infants from a variety of causes, but he wished to confine his remarks chiefly to that condition known as "haemorrhagic disease of the newborn," the onset of which occurred on an average about forty hours after birth. At the Liverpool Maternity Hospital the frequency of this disease was 1 in 405 cases, and his study was based on sixty-three, fifty-eight of which recovered. There was no apparent relation with the sex or weight of the child or with any abnormality in the mother. The aetiology was unknown and the condition so urgent that full haematological investigations were impracticable. In fifty-seven of his cases bleeding occurred only from the alimentary tract, which suggested the possibility of some local cause. A few mild cases appeared to require no treatment; the majority were relieved by the intramuscular injection of whole blood. In severe cases, or if this measure failed, the blood should be given intravenously.

Dr. JANET VAUGHAN reviewed published reports of the treatment of idiopathic thrombocytopenic purpura by various methods. These could be classified under three headings: (1) vitamins (C, P, and T); (2) hormones; (3) miscellaneous remedies. There was no evidence that vitamin C or P had any therapeutic effect, and the influence of vitamin T remained to be proved. The weight of evidence was also against the utility of ovarian extracts, the thyrotropic hormone, parathormone, and liver extract. The claim of Peck and Rosenthal that moccasin snake venom was a specific remedy had not been substantiated in other clinics, and their own results, when carefully examined, appeared far from satisfactory. Divergent results had been reported by careful observers from x-ray therapy, and it was suggested that there may be two types of the disease differing in their response to this treatment. Transfusion probably had value only in pre- and post-operative treatment. Representative figures for splenectomized cases were reviewed. The operative mortality for acute cases to-day was 13.6 per cent.; for chronic cases, 7 per cent. Excluding operative fatalities, in a total of 303 patients 217 recovered completely, forty were improved, and eighteen were not benefited. It was suggested that late relapses might be due to the presence of accessory spleens.

Dr. S. C. DYKE (Wolverhampton) spoke on the clinical pathology of haemorrhagic states. The first investigation should be a full blood count, and the collection of blood for this purpose gave also an opportunity of observing the bleeding time. A possible underlying cause was leukaemia, and in some forms of this disease, often accompanied by ulceration of the mouth, abnormal cells did not appear in the blood, which showed only leucopenia and anaemia. Sternal puncture would settle the diagnosis, but was unjustifiable in haemorrhagic states. If there were obviously few platelets in a stained film a platelet count should be done: the result was always under 50,000 in idiopathic thrombocytopenic purpura, and reduced to a less degree in anaphylactoid types, where a history of preceding urticaria or joint pains was also helpful. He preferred White and Lee's method of estimating the coagulation time to Dale and Laidlaw's, since it gave a much greater contrast in results: a time of over fifteen minutes obtained by the former method indicated a liability to severe haemorrhage during operation. He had found minor degrees of scurvy common, as indicated by ascorbic acid secretion, but treatment with this remedy was disappointing.

Dr. R. G. MACFARLANE discussed the mechanism of haemorrhage and haemostasis. It was usually considered that unduly prolonged haemorrhage occurred either when the coagulation time was lengthened or when there was a deficiency of platelets, but it could arise in the absence of either of these abnormalities. He had devised a new form of experiment which threw some light on the mechanism of haemostasis. It was possible to bring a single capillary under microscopical observation and to puncture it with a mechanically controlled needle. Blood escaped for a short time, after which the capillary contracted and remained empty, only refilling with blood three hours later. A rabbit given a powerful anticoagulant such that its blood *in vitro* remained fluid for a week, did not bleed unduly from a cut. He suggested, therefore, that capillary contraction caused the initial arrest of haemorrhage; undue haemorrhage might be primary owing to failure of this contraction, or secondary owing to failure or abnormality of clot formation during the period of contraction. He had treated seven cases of

haemophilia with the extract of egg-white recommended by Dr. Timperley, and had observed no change in the coagulation time except that in one case there was an increase. He disagreed entirely with the hypothesis on which this treatment was based.

Dr. W. A. TIMPERLEY (Sheffield) pointed out that local stypties were of limited value in haemophilia: something was needed which would control internal haemorrhage as well. He and his colleagues claimed that the extract of egg-white prepared by their method reduced the coagulation time and the liability to bleed: seven authentic haemophiliacs had been maintained in good health and free from haemorrhage in spite of a total of forty-one dental extractions, and in one case a street accident involving multiple injuries. The method of preparing the extract had been modified and two active substances identified, one a carbohydrate and one a protein; both were thermostable, but their activity was lost after two or three weeks, and the stored products sometimes came to have the opposite effect to that desired. A single dose should halve the clotting time within twenty-four hours; some samples had this effect within a few minutes. The treatment had to be persisted in, but eventually one dose a week might be enough. He concluded by asking for the indulgence of the profession while further attempts were being made to overcome difficulties in the process of extraction.

Professor G. A. CLARK (Sheffield) gave further particulars of the work described by the previous speaker. He pointed out that there were pitfalls in the method of extraction and suggested that some of those who had sought to repeat the work without success had not escaped these. The extract should be tested on cats for its capacity to reduce clotting time before being given to patients. The extract did not antagonize the action of heparin and did not reduce the clotting time *in vitro*: its action, therefore, must be indirect. Dr. HELEN M. M. MACKAY disagreed with Dr. Capon when he said that slight cases of haemorrhagic disease of the newborn required no treatment. A small haemorrhage might be followed by a very large one, and at the first sign an adequate intramuscular dose (say, 18 c.cm.) of citrated blood should be given at once and repeated in twelve hours. Dr. W. R. F. COLLIS (Dublin) recommended giving 10 c.cm. whole blood at once, repeating this in six hours and transfusing if this did not arrest the haemorrhage. Professor J. W. MCNEE (Glasgow), reverting to the subject of thrombocytopenic purpura, stated that he had examined spleens removed from patients with this condition and found them perfectly normal, not only in size but in microscopic structure. There was therefore no change in the spleen which would explain either the origin of the disease or the beneficial results of splenectomy. Dr. ALAN MONCRIEFF described a case of thrombocytopenic purpura in an infant, occurring at an earlier age than any previously recorded. He questioned the reliability of the tourniquet test for latent scurvy; the two arms might give different results, and the pressure advocated—90 mm. —was too high at least for children. Dr. R. E. STEEN (Dublin) recalled some experiences in which he had tested the possibility of reducing the clotting time in haemophilia: he had found that nothing would do this except whole blood or plasma. Professor S. P. BEDSON considered that the function of the spleen was to remove and destroy effete platelets. Their presence could be demonstrated by tearing out the fresh tissue or in tissue culture, but fixed material was unsuitable for studying the platelet content of the organ. Splenectomy or blockage with india ink caused a rise in the platelet count. Mr. E. R. FLINT (Leeds) maintained that the behaviour of the spleen could not be explained in such simple terms, and described a case in which the rise in the platelet count was much delayed after splenectomy.

Sir THOMAS HOUSTON (Belfast), in concluding the discussion, said that what they all found so difficult in face of haemorrhage was to decide how long it would continue and with what result. One case would respond at once to treatment and another continue in grave danger in spite of it. He described an experiment which appeared to show that adding normal platelets to haemophilic blood would cause it to clot rapidly, and suggested that some qualitative change in the platelets might be concerned in the disease.

Professor WITTS, in reply, adhered to his opinion that eventual relapse was fairly frequent after splenectomy in thrombocytopenic purpura, and that further operation in search of spleniculi was not advisable. He reiterated his failure to confirm the efficacy of Dr. Timperley's extract, and pointed out that cures for haemophilia were liable to attain undesirable publicity. He himself had been reported, quite incorrectly, to be exploiting a treatment devised by Rasputin! It was exceedingly difficult to assess clinical results in this disease, and the satisfactory repetition of Dr. Timperley's work was also extremely difficult owing to the changes which were being made in the process of extraction and the alleged instability of the product.

SECTION OF SURGERY

Wednesday, July 21

Surgical Treatment of Peptic Ulcer

With Professor P. T. CRYMBLE, president of the Section, in the chair, a discussion on the surgical treatment of non-stenosing peptic ulcer was opened by Professor JOHN MORLEY (Manchester).

Professor Morley said that in non-stenosing ulcer the trend was towards conservatism because of improved medical technique. Diet had been found of more value than alkalis, and the fractional test meal had proved a better guide to treatment than diagnosis. But there were failures, and the indications for surgery needed crystallizing. With regard to duodenal ulcer he was against too early intervention in cases in which there was bleeding, although he believed in operating as soon as a severe haemorrhage had been recovered from. Simple gastrojejunostomy was ineffective in the treatment of a bleeding ulcer, and he thought it best to include the duodenum in some form of gastrectomy. In the case of non-bleeding duodenal ulcers which had failed to yield to medical treatment, some surgeons advocated gastrojejunostomy and others partial gastrectomy. Because of the grave risk of anastomotic ulcer after the former—he believed the incidence to be about 10 per cent.—he favoured partial gastrectomy when the acidity was high. In women, in whom the incidence of recurrent ulcer was less and the acidity lower, and in elderly patients, he favoured gastrojejunostomy. As to gastric ulcer, the fear of post-operative recurrence was very much less and the dread of supervening carcinoma much greater. The incidence of the latter had been much exaggerated; he believed it to be a rare event. The difficulty was more that of distinguishing between simple and malignant ulcer, especially since there was a not uncommon slowly growing carcinoma simulating ulcer symptomatically. Because medical treatment was so often followed by relapse, he thought surgical treatment offered more in the treatment of gastric than of duodenal ulcer. Partial gastrectomy he regarded as the operation of choice. Gastrojejunostomy and simple excision were unsatisfactory. He himself was in favour of the Schoemaker modification of the Billroth I operation. In gastrojejunal ulceration there was only one operation of merit—the undoing of the anastomosis and the performance of a high gastrectomy.

Mr. NORMAN C. LAKE thought that the differences of opinion between physicians and surgeons on this subject depended on their different interpretation of what constituted a cure. The surgeon hoped to achieve a per-

manent relief of symptoms and to make the patient a completely effective member of the community, whatever his occupation might be. The physician was frequently satisfied if the patient's symptoms could be kept under by permanent restrictions of one sort or another, with a level of general activity well below his normal. Although, when the aetiology of peptic ulcer was known, treatment would be exclusively medical or prophylactic, at the present time, he claimed, surgical treatment more closely approximated a real cure. In the argument as to the relative values of gastrojejunostomy and partial gastrectomy, he, Mr. Lake, agreed with Professor Morley. The neutralization of the stomach contents in gastrojejunostomy occurred only in the region of the stoma, as was proved by post-operative test meals, and the stoma was subject to ulceration. Partial gastrectomy was the operation of choice. He reviewed a series of 320 partial gastrectomies, 269 of which were performed for peptic ulceration. The number of unsatisfactory cases was approximately 4 per cent.; anastomotic ulceration occurred in under 2 per cent. A mild microcytic anaemia followed in a few cases; no case of pernicious anaemia had been noted. Mr. Lake thought the strongest argument against surgical treatment was the operative risk, which he considered higher than was generally represented. On this account he was not prepared to operate unless the patient had had a good trial of various medical treatments. In conclusion, he thought that any assessment of results in peptic ulcer must be made with a recognition of the vagaries in the natural history of the disease.

Dr. CARL SEMB (Oslo) reviewed the subject from a Scandinavian standpoint. There medical treatment, with six weeks' rest and suitable diet, yielded good results in approximately half the cases, depending mainly upon the length of history. Two or three courses of medical treatment were tried before surgery was invoked. In Germany gastrojejunostomy had been more or less abandoned: in America, on the other hand, it was the operation most employed. This discrepancy had been explained as due to the more severe gastritis in the German cases. The Norwegian cases seemed to resemble the American, and gastrojejunostomy, for ulcers mostly in the juxtapyloric area, showed 60 to 70 per cent. good results, 15 to 20 per cent. fairly good results, and 10 to 15 per cent. bad results. Anastomotic ulcer was rare in Norway. The unsatisfactory results were usually found in young patients. But partial gastrectomy was more often performed. It gave better results, with a mortality rate as low. In 250 Norwegian cases partial gastrectomy was followed by some degree of anaemia in 45 per cent. of cases. But in this connexion there was a great difference between the sexes. Whereas 25 per cent. of male patients had an anaemia, usually of slight degree, 70 per cent. of female patients presented anaemia, which in 35 per cent. of cases was severe. In some cases of small duodenal ulcers in young patients a pyloroplasty was performed. Dr. Semb finally described a modification of the Billroth I operation in which the anterior wall of the duodenum was split to overcome technical difficulties by making a larger opening.

Colonel A. B. MITCHELL (Belfast) said that, because of the excellent results of gastrojejunostomy in cases of stenosis he had always produced an artificial stenosis at the time of operation in duodenal cases. He agreed with Professor Morley in deprecating too early interference in bleeding ulcer.

The PRESIDENT showed a series of lantern slides illustrating the steps of partial gastrectomy, and pointed out a number of anatomical variations which might be encountered.

Mr. G. GORDON-TAYLOR said he was almost in complete agreement with Professor Morley except for the particular form of anastomosis advocated. He had been impressed by the small incidence of microcytic anaemia found by Professor Morley. He also had found, as Dr. Semb had stated, that post-operative anaemia occurred chiefly in women. On that account he was loath to do a partial gastrectomy in women. But he was still in favour of early intervention for bleeding ulcers because of the impairment of liver and renal functions which followed delay.

Professor MORLEY, replying, rather regretted there had been so little fundamental difference of opinion. It was only for gastric ulcers that he preferred the Schoemaker operation; he preferred the Polya method for duodenal and anastomotic ulcers because it was more destructive of gastric function. Again, he thought anaemia less prevalent after the Schoemaker than after the Polya operation.

Gastroscopy in Dyspepsia

Mr. H. W. RODGERS read a short paper on the use of the gastroscope in cases of dyspepsia with normal x-ray findings. He said that any investigation of a dyspeptic patient, where radiology had failed to reveal a lesion, was incomplete without gastroscopy, since a small ulcer, a severe gastritis, and rarely a carcinoma might be demonstrated. He showed coloured slides to illustrate both normal and pathological processes. Gastroscopy was of especial value where dyspepsia still continued after operation, although the stoma could only be fully viewed in 50 per cent. of cases.

Mr. HAROLD C. EDWARDS referred to the disinclination in this country to adopt gastroscopy as a routine. He regarded it as invaluable, preventing many unnecessary laparotomies. The PRESIDENT referred appreciatively to this new method of demonstrating the pathology of the "living" stomach. Mr. HAROLD DODD thought that, because of the failure of radiology to demonstrate anastomotic ulcers in his series, their incidence had probably been underestimated. He advocated routine gastroscopy in cases not doing well after gastro-jejunostomy. Mr. LAKE described a form of gastroscope he had employed some fifteen years ago. This he had introduced through the stomach wall after laparotomy, and from it he had learned a great deal of lining pathology. Professor L. R. BRAITHWAITE (Leeds) wished to know if gastroscopy could throw any light on duodenal regurgitation, but Mr. RODGERS replying stated that the procedure was carried out under abnormal physiological conditions both of the stomach and of the patient, and that therefore little information was likely to be obtained.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Wednesday, July 21

Professor G. C. LOWRY, the president of the Section, was in the chair. Professor HERBERT THOMS of Yale University, whose paper appears in this week's issue of the *Journal* at page 210, was not able to be present.

Prontosil in Puerperal Infections

Mr. G. F. GIBBERD opened a discussion on prontosil and similar compounds in the treatment of puerperal infections due to the haemolytic streptococcus. His paper was based on 157 cases of puerperal infection treated at Queen Charlotte's Hospital between January, 1936, and March, 1937. After a preliminary reference to the various types of the drug and the dosage used, he compared this series of cases with a control series treated in the hospital for the two years before the introduction of the new drug. The cases were divided into groups according to the clinical invasion of the infection in the patients, and a comparison of the results in each case with the parallel set of cases in the control series was shown in a table. A second table showed the comparison between the present series and the control series in the duration of the illness (interval between confinement and discharge from hospital) in non-fatal cases in which an inflammatory mass was demonstrated beyond the limits of the birth canal. This table brought out the much shorter time spent in hospital

by patients who had been treated with prontosil. In conclusion, Mr. Gibberd pointed out that the mortality rate from haemolytic streptococcal infections had been much reduced by the new drug. It was necessary to consider whether the improvement since January, 1936, was due to the efficacy of the treatment or to a change in the virulence of the prevalent organism. Both factors might be concerned. In non-fatal cases in which tissues beyond the limits of the birth canal had been invaded there was some clinical evidence that the new drug did actually hasten the resolution of the inflammatory process. This seemed to show that the treatment rather than a change in the virulence of the organism was responsible for the improvement.

Dr. DORIS E. BROWN (Belfast) reported thirty cases of puerperal sepsis due to Group A haemolytic streptococcus that had been treated with prontosil in the Royal Maternity Hospital, Belfast, between May, 1936, and May, 1937. Of the thirty cases, twenty had a local infection of the uterus, seven were cases of septicaemia, and three had general peritonitis alone. Of the twenty cases of local infection, nineteen appeared to be benefited by prontosil, and there were no deaths in this group. For three years before the introduction of prontosil the death rate for cases of septicaemia was 87.5 per cent., and the mortality for all cases due to infection by the haemolytic streptococcus was 23.53 per cent. Since the use of the drug the mortality rate in cases of septicaemia was 28.57 per cent., and for all cases of puerperal infection 6.6 per cent. Prontosil had also been given to twenty-one patients with mastitis. In twenty resolution was complete, and the other patient was left with a small residual abscess which rapidly cleared up on incision. Of eighteen patients with mastitis —previous to the introduction of prontosil—nine developed breast abscesses, which were incised. Mr. L. CARNAC RIVETT emphasized certain points in the figures presented by Mr. Gibberd—for example, the sudden and dramatic drop in the cases of septicaemia from an average mortality of 71 per cent. to a mortality of 27.3 per cent. Professor H. J. DREW SMYTHE (Bristol) referred to a year's use of prontosil and its derivatives. The mortality rate was practically the same in the series treated with prontosil as in those not so treated, but the main point was the rapidity of cure in the treated cases. Dr. BETHEL SOLOMONS (Dublin) felt there was a grave danger in the drug giving a false sense of security. The general practitioner must be made to realize that he must not produce cases of failed forceps in the belief that prontosil would always act as a cure for the ensuing septicaemia. They had gone through the gamut of dettol cream, vaccines, and other possible cures for sepsis, but real cure still remained in prevention, which could only be accomplished by a knowledge of normal obstetrics as taught by skilled teachers. Professor J. CHASSAR MOIR (Oxford) said that a few clinical reports had appeared which suggested that in certain individuals protracted prontosil therapy might dangerously interfere with the blood-forming mechanism. This urgently called for investigation. It seemed unwise to give prontosil or its allies as a routine prophylactic measure. He also referred to the remarkable effect the drug had in combating *B. coli* infection of the urinary tract. In most cases the urine could be rendered sterile in about five days. This might account for the beneficial action of the drug in some cases of puerperal pyrexia due to a coincident urinary infection. Dr. J. ARTHUR H. SHERWIN (Melbourne, Australia) also joined in the discussion.

Habitual Abortion

Mr. PERCY MALPAS (Liverpool) in a paper on the problems of habitual abortion first presented a statistical review from which he concluded that perhaps eighteen out of every hundred pregnancies ended in abortion, seventeen due to casual random influences and only one to the presence of a recurrent factor. The presence of such a recurrent factor might be inferred with reasonable certainty after three successive abortions. He believed that recurrent stillbirths, recurrent abortions, and recurrent toxaemias and accidental haemorrhages were sometimes closely allied conditions. Possible aetiological factors which he discussed were twinning, foetal malformations, familial tendencies, chronic maternal diseases, syphilis, poor general health and nutrition, obstetric trauma, chronic nephritis, and recurrent toxaemias and accidental haemorrhages. One or more of these factors were found in sixty-five of the 115 cases he reviewed. In the remaining fifty no cause could be found; from a general consideration of these cases only two features emerged: a large number showed a marked tendency to obesity, and in those cases in which pregnancy was ultimately carried to term the children were under weight, indicating some metabolic failure.

Nine of his cases received wheat-germ-oil therapy, and of these two went to term. He thought that vitamin E deficiency was not a constant factor in recurrent abortion. Ascorbic acid might also play some part in controlling intra-uterine development. Four of his patients were treated with progestin, two successfully. Progestin therapy was probably the most effective known treatment for certain cases of habitual abortion. Thirty-three patients were treated by injections of organic arsenical compounds; in no less than thirteen of the twenty who gave birth to living children no cause had been detected for previous abortions, whereas among the failures only two cases belonged to this group. Mr. H. L. HARDY GREER (Belfast) opened the discussion. He regarded proluton as an endocrine preparation of some value.

Dr. O'DONEL BROWNE (Dublin) congratulated Mr. Malpas on his investigation, and stressed the fact that syphilis was only found in 5 per cent. of such cases, and in only approximately 50 per cent. of all cases of abortion could the actual cause be discovered. His own experience with proluton was most satisfactory; he was more reserved in his view on the use of wheat-germ-oil. Dame LOUISE MCILROY stressed the importance of food deficiency—especially in calcium—as a factor in recurrent abortions. Dr. J. J. HOLLAND (Perth, Western Australia) stated that sufficient thought was not given to the male partner, in whom the fault lay more often than was stated. It was useless to give all the methods of treating the female when she had no chance of carrying the pregnancy because of a fault in the male.

Hystero-salpingography

Mr. V. B. GREEN-ARMYTAGE (London) read a paper on hystero-salpingography, its obstetrical and gynaecological importance.

Mr. Green-Armytage remarked that the insufflation test for patency of the Fallopian tubes was open to criticism. In the first place a negative finding at a pressure of even 250 mm. Hg was often due to uterine spasm compressing the isthmial part of the tube, and not to any lack of patency. Secondly, insufflation gave no information as regarded both tubes. Thirdly, no evidence was obtained as to the site of occlusion or as to the existence of any developmental abnormality, as, for example, unicornuate uterus. Hystero-salpingography, on the other hand, he believed to be a precise and scientific method. It should be applied before and after all plastic operations upon the tubes; it was physically and psychologically of great prognostic value; and its therapeutic effect was double that of a simple insufflation. Discussing occlusion of tubes Mr. Green-Armytage further stated that in a consecutive series of 300 cases seeking relief for sterility the tubes were blocked in only 14 per cent., and in only 12 per cent. of these cases could the condition be attributed to gonorrhoea.

Dr. BETHEL SOLOMONS said the most important fact elicited from this paper was that the "doubting Thomases" who would not even try plastic operations on the tubes must have been silenced. This series of films showed what

he had endeavoured to prove for many years—that operations on the tubes produced a small but important percentage of success in many hopeless cases. He had started the first *x*-ray department in connexion with a maternity hospital in 1926 at the Rotunda, and he had done many salpinograms since. Ethidol, he believed, gave the best results, and he took a second film ten minutes after the first to eliminate spasm of the uterus. He had observed that very severe puerperal sepsis was seldom followed by sterility, but a mild degree of sepsis with parametritis had often been followed by closure of the tubes. Salpingograms should be taken as a routine after plastic operations on the Fallopian tubes. Professor CHASSAR MOIR and Professor LOWRY congratulated Mr. Green-Armytage on his excellent results, and urged the continued use of this method of dealing with the investigation of tubal disease.

SECTION OF PHARMACOLOGY AND THERAPEUTICS INCLUDING ANAESTHETICS

Wednesday, July 21

Variation in Response to Drugs

With the President of the Section, Professor E. B. C. MAYRS (Dunmurry) in the chair, Professor A. J. CLARK (Edinburgh) opened a discussion on individual variation in response to drugs.

Professor Clark said that the method of determining the minimum lethal dose of a drug by giving varying doses to a small number of animals was inaccurate because no account was taken of individual variation, a factor which depended both upon the population and upon the drug. The extent of this variation could be reduced by making the population as uniform as possible, but, even so, animals still showed wide variation in their response to drugs. If the shape of the characteristic curve from 10 per cent. to 90 per cent. mortality was established the laws of probability could be applied, and it was possible to calculate the chance of a mortality of 1 in 1,000. Characteristic curves could also be obtained by plotting the dosage on the logarithmic scale. So far as human variations to drugs were concerned, it had been shown that 16 per cent. of a series of patients were narcotized by 75 per cent. of the median narcotic dose of sodium amytal, a variation comparable with that found for the lethal action of this drug in animals. Likewise, 50 per cent. of the population were narcotized by 80 per cent. of the dose of avertin needed to narcotize 84 per cent. This was also comparable with animal experiment. Professor Clark stated that individual variation was an unattractive subject because its existence constituted a limitation to therapeutic measures of an annoying character. It seemed probable that the extent of individual variation was consistently underestimated, because if an individual representing an extreme of variation happened to be encountered in a small group, the result was apt to be discounted as an accident. The evidence available, however, suggested that whenever it was possible to measure quantitatively the effects produced by a drug in a large population an orderly distribution of variation in response was revealed.

Professor J. H. GADDUM said that, although it was possible to make some allowance for such factors as age, sex, weight, and the general condition of patients, he considered that a large part of the individual variation to drugs was unpredictable. A chance must always be taken when prescribing, but he liked to know as far as possible the odds for and against. He foresaw the time when it would be possible to predict the percentage of cures to be expected from any given dose and to estimate exactly the danger involved in increasing the dose to any given extent. At present there was a lack of data of a quantitative nature in connexion with human response to drugs, and there were two ways in which this information could be obtained. In some cases it was possible to measure the sensitivity of the individual—as, for example, when digitalis was administered and bradycardia observed. The amount consumed measured the sensibility of the patient, and if a large number of such figures were available it would be possible to calculate the variability and also, possibly, the effect of age, sex, and weight. The second method was to give the same two doses each to a series of cases. From the percentage of reactions it was possible to calculate the variability. For example, if the percentage of toxic effects due to two different doses of an organic arsenical drug were known, it was possible to calculate the probable percentages corresponding to other doses and thus to know what dose would be quite safe.

Dr. GEORGE GRAHAM drew attention to the local reaction which might follow the administration of insulin. He was able to distinguish four groups. In the first complaint was made of a stinging sensation as soon as the insulin was injected. This seemed to depend upon the fact that the insulin employed was not isotonic to sodium chloride. In the second group complaint was made of red, irritating reactions, resembling those sometimes occurring after the injection of a vaccine. If this phenomenon was observed a trial should be made of all the different brands of insulin, and usually one would be found which would cause little or no pain. It was possible, however, to desensitize a patient suffering from this type of reaction. The third group of patients comprised those in whom a hypertrophy of the subcutaneous tissues resulted in a fatty tumour; and in the fourth group a local fat atrophy caused a depression in the skin. If these conditions were noticed the patient should be persuaded to vary the site of injection as much as possible and another brand of insulin should be tried.

Dr. P. MACCARVILL (Dublin) said that from the dermatological point of view individual variation in response to drugs was without limit. Whether or not a person became sensitive to a substance depended upon three factors: his personal idiosyncrasy; the dose of the antigen; and, if the dose of the antigen was sufficiently large, no personal idiosyncrasy was required. It was fortunate that the skin as an organ was exceptional in the intensity of its variations and sensitivity, for, if other organs were equally sensitive, still greater difficulty would be experienced in determining both therapeutic and lethal doses. The promiscuous use of iodine, picric acid, and similar antiseptics caused frequent trouble, especially when continued after the manifestation of obvious reaction in the skin. Repeated parenteral administration of arsenic and gold after advance warnings in the form of reddened forearms or moist flexures was asking for trouble; yet very few cases of exfoliative dermatitis occurred without these previous warnings.

The PRESIDENT was impressed by the fact that pharmacologists evidently were interested in quantitative variations and clinicians in qualitative variations. If a simple method could be found of estimating quantitative variations in clinical practice it would be of considerable value.

Dr. P. C. P. INGRAM (Newport, Mon.) referred to the frequency with which powerful arsenicals were administered without previous clinical examination and without untoward effect. The nervous tension experienced by the syphilitic patient undergoing treatment might be a factor in the production of undesirable reactions. Dr. J. F. BROCK (Cambridge) asked if it was believed that idiosyncrasies were inherited or acquired, and if they were met with in children. Professor H. S. RAPER (Manchester) cited experiments performed many years ago in which mustard gas diluted with benzine was applied to the forearm of many subjects. There was considerable variation in the reactions produced by a substance with which the subjects could not previously have come into contact. Professor DAVID CAMPBELL (Aberdeen) considered that if there was a variation of 1 to 4 in the fatal dose of a substance the use of intravenous anaesthetics constituted a very real danger. Likewise, accuracy could not be

expected from the administration of digitalis when the dosage was based solely on the weight of the patient. He believed that drugs should be given singly and not in mixtures, and that the dose should be increased until the desired effect was produced.

Iron Therapy in Hypochromic Anaemia

Dr. J. F. BROCK (Cambridge), in a paper on this subject, said that nowadays perhaps the action of iron in this condition was less perfectly understood than it was five years ago. This was because the result of balance experiments revealed a number of cases of hypochromic anaemia in which iron deficiency was not the sole mechanism at fault. This type of anaemia was often associated with an inadequate diet or with chronic loss of blood; but achlorhydria was sometimes a factor. Balance experiments demonstrated that when patients suffering with this condition were given enough iron by the mouth 11 per cent. to 32 per cent. of the amount ingested was retained in the body, although a consideration of the increase in the haemoglobin percentage suggested that the amount retained in the blood was very much less. Many patients with a mild degree of hypochromic anaemia improved when given relatively small amounts of iron, but he thought that in general the daily amount of iron administered should not be less than 300 milligrammes. This could be prescribed in the form of pil. ferri, 45–90 grains, or of iron and ammonium citrate, 60–90 grains, a day. The intramuscular injection of iron preparations was useless; if sufficient iron to cure the anaemia were injected toxic symptoms might occur. All forms of organic and colloidal iron were relatively ineffective, and the concurrent administration of other drugs, such as copper, manganese, and cobalt was not indicated. It was possible that in a small group of these patients iron had an additional effect upon the intestinal tract, but it was impossible to distinguish this group clinically. Sufficient iron should be given to enable the patient to respond, and an adequate diet was also desirable.

Dr. J. H. THOMPSON (Croydon) inquired if there was any advantage in administering glycerin with iron and ammonium citrate. Professor CLARK said that, as the importance of the duodenum as an absorbing centre was being increasingly recognized, he wondered if the administration of massive doses of iron altered the reaction of the contents of this organ. It was further possible that ferrous salts had a buffering effect. Professor CAMPBELL pointed out that Dr. Brock had already cited a case with achlorhydria in which the absorption of iron was greater than in cases with normal acidity. Professor GADDUM considered that the concurrent administration of vitamin C promoted the absorption of ferrous salts.

In reply Dr. BROCK stated that little was known regarding the absorption of iron from the intestine, but he felt that physico-chemical reactions played an important part in this process.

SECTION OF ANATOMY, PHYSIOLOGY, AND BIOCHEMISTRY

Wednesday, July 21

Anatomy and Physiology of the Sex Glands

The President of the Section, Professor E. C. DODDS, opened a discussion on the anatomy, physiology, and biochemistry of the sex glands. Professor Dodds's paper was published in last week's *Journal* at page 163.

Dr. A. S. PARKES referred to the part played by the sex hormones in the development and treatment of prostatic enlargement. He reviewed the evidence which led to the suggestion that prostatic enlargement was due to excessive oestrogenic activity of the testis, and showed that both progesterone and testosterone could inhibit the oestrous changes.

Dr. P. M. F. BISHOP stated emphatically that anterior pituitary preparations were ineffective when administered by mouth. He mentioned that examinations of vaginal smears and the production of "threshold" uterine bleeding were useful indications of the physiological dosage of oestrin in women.

Dr. J. M. ROBSON (Edinburgh) showed that luteal function could be maintained in hypophysectomized rabbits by means of oestrin. In twenty-one out of twenty-two cases of pre-eclamptic toxaemia the administration of progesterone had prevented the onset of fits. None of these twenty-two patients had died, as compared with a mortality of 10 per cent. in thirty-one control cases. Finally he referred to the prolonged and potent oestrogenic activity of triphenyl ethylene when administered by mouth.

Mr. R. K. BOWES described a method of obtaining endometrial strips by using a modified Randall's curette. Direct assessment could thus be made of the progress of endocrine therapy in menstrual disturbances. He had obtained satisfactory results by treating with oestrin cases of kraurosis, senile vaginitis, and dyspareunia occurring at the menopause. Gonadotropic extracts, he thought, must be given to supplement oestrin to obtain repetition of the menstrual cycle in cases of amenorrhoea, and he had been favourably impressed by "antex" used in a small series of cases of amenorrhoea, oligomenorrhoea, and gross irregularity of menstruation.

In the absence of Mr. W. R. WINTERTON the president showed some slides indicating the appearance of the human vaginal smear at the time of the menopause and during the phase of full oestrous activity. Dr. PARKES suggested that the changes in the vaginal smear might be due solely to the psychological effects of treatment. Dr. Bishop had, however, obtained no such changes while administering an inert material for a preliminary control period. Dr. R. D. LAWRENCE asked whether there was danger of inducing carcinomatous changes by the administration of oestrin. Professor DODDS believed that no such danger existed if oestrin were employed solely for the purpose of reproducing physiological phenomena. He felt, however, that triphenyl ethylene, the synthetic oestrogenic compound referred to by Dr. Robson, should be employed clinically only with considerable caution.

The Parathyroid Glands

Professor W. J. E. JESSOP (Dublin) read a paper on the clinical bearings of the parathyroid. These glands secreted a hormone the primary object of which was the maintenance of the blood calcium at an optimum level for the control of the neuro-muscular system, and this was attained by controlling the balance between deposition and absorption of calcium salts in the bony reservoirs. He reviewed the clinical manifestations of hypoparathyroidism, of which tetany was the chief. Tetany might also be caused by rickets and alkalosis. It had been recently suggested that otosclerosis was a manifestation of hypoparathyroidism. Hyperparathyroidism occurred in the presence of a parathyroid tumour, a case of which he gave a full account. Dr. PARKES inquired whether there was any evidence of excessive function of the parathyrotropic hormone of the pituitary in cases of parathyroid tumour, and whether this hormone had been employed in hypoparathyroidism. Professor JESSOP answered both questions in the negative. Professor DODDS had seen cases in which tetany had persisted for some time following an operation for Graves's disease but had eventually cleared up. Professor JESSOP suggested this might be due to gradual hyperplasia of the remaining parathyroid tissue.

Recent Work on Insulin

Professor A. WORMALL, in a paper on recent work on the chemistry of insulin, referred to the various methods of studying the constitution and structure of insulin, and he outlined the present position with regard to the chemical properties of this hormone. The crystallization of insulin

by Abel, and more recently as a zinc salt by Scott, was mentioned; insulin was a protein which contained fewer different amino acids than most proteins. There was evidence, from the work of various authors, that the cystine, glutamine or glutamic acid, tyrosine, and the free amino groups were essential for the characteristic hypoglycaemic action of insulin. The speaker described experiments, carried out by his colleagues and himself, which showed that blocking of the free amino groups by the action of phenyl *iso*cyanate or of benzyl carbonyl chloride caused complete inactivation of insulin. He also referred to investigations which had failed to demonstrate any antigenic activity of insulin.

Dr. R. D. LAWRENCE, in a paper on the use of protamine insulin and similar preparations, said that he had been unable to confirm the successful results claimed by Szent-Györgyi for the treatment of diabetic ketosis with succinic acid by mouth. With regard to insulin it seemed unlikely that it would ever be available for oral administration. Protamine insulin ("retard" insulin), however, was more lasting in its effect than soluble insulin, because it was injected as a precipitate which was only slowly dissolved and utilized at the normal reaction of the tissues. Its effect lasted for twelve to sixteen hours. Zinc protamine insulin was even more stable, and its effect lasted for twenty-four to thirty-six hours. Owing to the slow absorption of these compounds the amount of insulin circulating at any one moment was less than immediately after an injection of soluble insulin. The blood sugar rose higher, therefore, after a carbohydrate meal. Such hyperglycaemia, however, was not attended by ketosis. Owing to the prolonged effect of the new compounds there was a danger of hypoglycaemia occurring during the night, and it was wise to prescribe a buffer meal of carbohydrates before going to bed.

Dr. GEORGE GRAHAM agreed with Dr. Lawrence in regarding the new insulin compounds as being valuable additions to the list of diabetic remedies. They should, however, be used with caution, for the symptoms of overdosage were less apparent than in the case of soluble insulin, and the patient was liable to pass without warning into hypoglycaemic coma. Dr. PARKES mentioned the possibility of the development of anaphylactic phenomena after the administration of insulin obtained from different sources. Professor WORMALL thought that changing the brand of insulin was unlikely to arrest the anaphylactic phenomena. Professor DODDS had found that combination with zinc had prolonged the activity of both vasopressin and histamine, and asked whether this was due to a direct action on the tissues at the site of injection. Both Professor WORMALL and Dr. PARKES believed this to be the case.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

Wednesday, July 21

Early Diagnosis of Intracranial Tumours

With Dr. GEORGE RIDDOCH, President of the Section, in the chair a discussion took place on the early diagnosis of intracranial tumours.

Dr. F. M. R. WALSHE said that nowadays there was a danger of technique triumphing over reason in this sphere of medicine. Taking the clinical history in cases of intracranial tumour was an art which had to be learned; for instance, patients should not be questioned in such a way as to suggest the answers the questioner had in mind. The discovery of clinical signs should always be followed by a careful assessment of the relative symptoms. In his opinion many of the modern expensive technical investigations were unnecessary; too much reliance was placed on them and too little importance was attached to the due appreciation of the clinical evidence. Dr. Walshe, discussing briefly Cushing's report on 2,000 cases of intracranial tumour, mentioned that several cases had been wrongly sent for cranial operations, and in many others radiography could not have afforded an early diagnosis. Dr. Walshe referred to four features in the onset. (1) There was first the occurrence in a middle-aged patient, who had never been so afflicted before, of a series of recurrent epileptiform fits which were separated by intervals free from all subjective or objective symptoms. These generalized fits were more common than the localized ones. (2) Signs of raised intracranial pressure were not in some cases associated with vomiting, and the latter was not always projectile in nature. Slowing of pulse was uncommon except in rapidly growing tumours; it was more common in subdural haematoma than in intracranial tumour. (3) In other cases there were signs of a slowly progressive local lesion of the brain. He pointed out that slowly developing weakness of one side of the body in the middle-aged might be due to paralysis agitans. (4) When the onset suggested a malignant process it should be remembered that carcinoma of the brain was frequently secondary to a primary carcinoma of the lung. Such secondary growths were usually multiple. It was difficult to make a localizing diagnosis. Signs of meningitis might be present, and should be correctly assessed. There was usually a confused clinical picture in these cases, but progressive loss of weight with cachexia was often a significant feature. In any event the early diagnosis of an intracranial tumour was difficult, and might at times be impossible. Tumours might even develop without any clinical manifestations, and in few cases was diagnostic certainty permissible.

Mr. N. M. DOTT (Edinburgh) stated that three questions had to be answered. (1) Was a tumour present? (2) If so, where was it located? (3) What was its nature? Clinical neurology was the principal factor in diagnosis. Mr. Dott devoted his speech mainly to indicating the value in diagnosis of various special accessory methods of technical investigation, and showed illustrative lantern slides. Cerebral radiography revealed local signs of calcification or osteoporosis in tumours, and there might be evidence of skull erosion. Sometimes these signs were forthcoming before the onset of clinical symptoms. Examination of the cerebro-spinal fluid should be a routine procedure, but in cases of increased pressure a lumbar puncture should only be performed in a hospital where it was possible to operate immediately afterwards. A suggestive finding was a pressure of over 250 mm. of water; another one was an increase of protein in the fluid without a corresponding rise in the cell count. Ventriculography might be dangerous in low-pressure cases owing to the risk of compression of the brain stem, or risk to life might be incurred owing to the cerebellum being pressed upwards. Ventriculography should be the last diagnostic step to be undertaken, and be performed only when the conditions were suitable for an immediate operation. By these procedures an accurate differential diagnosis might be obtained. Cerebrovascular radiography gave a more intimate knowledge of the tumour itself rather than of its anatomical position in the skull, the state of the arterial and venous vascularization of the tumour could be precisely determined. The anatomical relation of the tumour must be carefully defined. The objective of the diagnosis was the cure of the patient, and therefore treatment was an essential factor in the diagnostic investigation. The investigator must consequently be fully familiar with the possible lines of treatment. A diagnostic physician might be seriously handicapped if he was ignorant of the surgical possibilities in any case, and hence both surgical and medical specialists must be consulted.

Dr. H. L. PARKER (Dublin) said that the first line of attack lay with the general practitioner, who could detect cases before, for example, irrecoverable blindness developed. Memory might be clouded even at the beginning, and symptoms of importance be thus not reported. Smell and taste might be affected early, and vision only later. Cases

were cited to illustrate these points, and it was emphasized that loss of memory might be an important early symptom, especially when associated with a habitual tendency to repeat statements. Hemianopsia was often an early symptom, as was also loss of hearing in one ear. These first symptoms were of great diagnostic significance, since later ones might be confusing. Dr. Parker strongly favoured team work in investigation by one or two surgeons and physicians who had been previously acustomed to work together. The neurologist was essentially a man of thought, predisposed to waiting for elucidatory evidence; the surgeon was a man of action, and might be dangerously precipitate. These lines of approach should converge in the successful treatment of the patient. Spinal puncture might be risky in these cases, especially when the tumour was situated above the tentorium. In a technical investigation the order of precedence should be the general practitioner, the neurologist, and the surgeon in conjunction with the neurologist. Early diagnosis and correct localization were the primary objectives.

Mr. A. A. McCONNELL (Dublin) agreed that the early diagnosis of intracranial tumour was essentially a matter for the general practitioner. When there was evidence of something encroaching upon the cranial cavity the diagnosis of a cerebral tumour was not infrequently correct, since these lesions were not uncommonly found, for instance, in post-mortem examinations. Only in young patients was headache an early significant finding. Vomiting, with or without headache, was significant when there were intervals in which the appetite was good and the working capacity normal. Surgeons should use all the clinical methods employed by physicians, for operative judgement depended on clinical knowledge more than on the knowledge derived from technical investigations, though the latter were essentially parts of the subsequent operative treatment, guiding, as they did, its various lines in different cases. They were supplementary, and did not replace clinical methods.

Dr. T. TENNENT said that psychological symptoms often appeared early in cases of intracranial tumour. Mental symptoms were more frequent in left-sided lesions and supratentorial growths. They included difficulty in concentration, loss of memory, irritability, confusion, stupor, worry about personal health, and suicidal tendencies. Erroneous diagnoses might, therefore, be easily made by the general practitioner. Functional mental disturbances in cases of tumour might simulate those in psychotic states, and were often chronic and resistant to treatment. There might be an exaggeration of pre-existing personality traits, such as homosexuality. Excitement symptoms might be insidious as regards their evolution, and they were often associated with lesions of the frontal lobes, but differentiation in this regard was of uncertain value. When the organic symptoms were predominant their duration was short and the deterioration of the patient rapid. No mental symptoms could be associated with any one special lesion of the brain.

Mr. W. GREY WALTER, speaking as a physiologist who had applied the measurement of varying electrical potentials to the brain tissues (electro-encephalography), described the uses and limitations of this technique, and reported a series of cases dealt with at the Maida Vale Hospital. He remarked that this method involved no danger or discomfort to the patient, and the time of examination was only one-quarter to half an hour. The appearance of rather slow pulsations of the potentials were amplified and recorded; their origination could be localized by technical means. The term given to them provisionally was "delta waves," in comparison with the "alpha waves" of Buerger, which constituted the normal rhythm. These delta waves were caused by the cortex in the neighbourhood of the tumour, and not by the growth itself. They were due to induced disturbance of the cerebro-spinal fluid or of the circulation. If the tumour was small or superficial, or did not involve the cortex very much, the waves might be absent in some cases. In other diseases they might also be absent, and the results could not then be trusted. This method of investigation was useful only when the short delta waves were present and the cortex was affeceld by the tumour. Cerebral tumours might be confused with idiopathic epilepsies, but the foci of these abnormalities were fortunately only placed in one or two definite parts of the brain, and the waves presented slight differentiating abnormalities. While this method was only available for the diagnosis of intracranial tumours, it might nevertheless be of very considerable value in them, indicating the way in which the cortex was functioning. The technique had not yet been made suitable for use by general practitioners, but in special cases of difficulty it might be employed by specialists with advantage.

Dr. A. GURNEY YATES (Sheffield) stressed the danger inherent in lumbar punctures. There might be no time for an operation to relieve dangerous symptoms, and careful precautions must therefore be taken. The fluid should be drawn off slowly and in small amount. An equal quantity of saline solution should be immediately injected; this might possibly relieve dangerous symptoms. Team work was always preferable in cases of intracranial tumour; an ophthalmologist and a deep-ray therapist might be helpful. Dr. J. PURDON MARTIN said that it was necessary to have more information from those who practised the newer methods of investigation as to their dangers and also of the proportion of cases in which reliable positive evidence was obtained when medical and neurological investigations had failed. In practice the problem was whether, when a cerebral tumour was suspected, one was justified in submitting the patient to ventriculography. Dr. H. G. GARLAND (Leeds) added that the most important way in which a cerebral tumour could be detected with certainty at an early stage was to educate the general practitioner to recognize the common first manifestations. He thought that the cases of visual failure, epilepsy developing in adult life, focal neurological syndromes, and mental changes were usually sent for specialist advice at an early stage, so that the recognition of the headache due to intracranial pressure was one of the most fundamental points in early diagnosis. The practitioner should be trained to analyse the characters of headache, for in many cases careful analysis would lead to an early diagnosis of intracranial tumour. Dr. W. RITCHIE RUSSELL (Edinburgh) stressed the importance of mental changes. It was very regrettable that cases of tumour should so often be sent to mental hospitals. Over the age of 45 to 50 the classical signs of brain tumour were often absent, and only insidious changes in the patient were noticeable at first. Professor E. MAPOTHER cited illustrative cases of moral degeneration as an early symptom of a cerebral tumour. There was not always an accentuation of the pre-existing mental disposition. Sometimes exastly opposite temperamental changes appeared—for instance, intemperance and dishonesty in previously strictly upright characters. This point was not yet adequately realized.

Replying to the discussion, Dr. WALSHE insisted on the need for neurological education. He thought that the electro-encephalograph was not yet scientifically safe. Mr. DOTT, agreeing that the discussion had been most instructive, stated that some cases were quite unsuitable for lumbar puncture. In focal epilepsy arterioradiography could be very helpful. The value of this and other methods could be best assessed by those who used them repeatedly. Thorotrast, though a carcinogenic substance, had done no permanent harm in his experience to patients in middle age, but he was doubtful whether it should be used for young patients. Dr. PARKER upheld the diagnostic value of encephalography. It was still in its first year of development in this respect, but some failures had been set off by many successes. The PRESIDENT, summing up, said that as yet there was no short cut to diagnosis. Clinical examination still remained paramount. The psychiatric aspects of intracranial tumours needed more investigation by psychologists and neurologists.

SECTION OF ORTHOPAEDICS

Wednesday, July 21

Fracture of the Neck of the Femur

After the chair had been taken by Mr. S. T. IRWIN, president of the Section, a discussion on operative treatment and results in fracture of the neck of the femur was opened by Professor E. W. HEY GROVES (Bristol).

Professor Hey Groves pointed out that Smith-Petersen's successful use of a steel nail in the treatment of this fracture was a triumph of practice over theory, for it had long been agreed that the use of metal for the internal fixation of fractures was to be avoided whenever possible. For sound physiological reasons the trend of almost all recent work had been away from the use of metal. There was now a danger that Smith-Petersen's method might suffer from the excessive popularity that had been the downfall of Lane's and Lambotte's methods, and the speaker hoped that readers of subsequent papers would dwell on the limitations and possible dangers of pin fixation as well as on its undeniable merits.

Professor SVEN JOHANNSON (Gothenburg) gave a detailed account of the blind method for insertion of the Smith-Petersen nail that he had used during the last six years. The results were striking. In all, 179 cases had been operated on with a mortality (from all causes—early and late) of 10 per cent. Of the patients who lived 95 per cent. had good bony union and function. In twenty-six cases the nail had been removed because it had worked out laterally and was causing pain; at the time of removal bony union was already well advanced.

Dr. ELLIS JONES (Los Angeles) thought that the acceptance of Smith-Petersen's method was perhaps a little too enthusiastic, and that surgeons must not (to quote the words of Sir Robert Jones) forget that "the problem before each of us is how to improve our skill and technique in both the operative and manipulative treatment, and how to determine what method we must adopt in each individual case to give our patients the surest, safest, and most complete restoration of function." The following methods required consideration: (1) the manipulative method of Whitman, which necessitated fixation of the limb in plaster; (2) internal fixation with metal, which rendered plaster unnecessary (a useful alternative to Smith-Petersen's method was that described by Austin Moore, who used three separate small stainless steel nails inserted through the trochanter and neck into the head of the femur); (3) internal fixation with an autogenous bone graft, where again a period of fixation in plaster was necessary.

Dr. Jones described his own operation as an alternative to the tibial bone graft favoured by Albee. Only one incision was required, seeing that the graft was obtained from the great trochanter and the upper end of the shaft of the femur. The removal of this graft enabled the surgeon to inspect the fracture site and confirm the accuracy of the manipulative reduction. A hole was now drilled through the trochanter and neck into the femoral head, and the graft was inserted. Being a square peg in a round hole it fitted snugly, and as it was cancellous bone of the same type as that found in its new bed vascularization was rapid. Further fixation was obtained by the insertion of two Moore's pins. Although the results of this comparatively new procedure were most encouraging, it must not be said that this or any other method was the method of choice. In the hands of Leadbetter, Whitman's method was now giving bony union in 71 per cent. of cases ranging in age from 40 to 90 years, and it was probable that manipulative reduction and plaster fixation was still the method of choice in young patients in whom the disadvantages of plaster fixation were negligible. In older patients bone grafting or pin fixation were preferable, with a slight bias in favour of pin fixation in the aged.

Dr. ERIC I. LLOYD was disappointed at the absence of specific reference to late results in Professor Johannson's series of cases. It was by no means certain that an early success was permanent. In two of his own cases he had removed pins sixteen months and twelve months after operation (by which time they had ceased to have any useful function) and slipping at the site of fracture had promptly followed. The radiographs had suggested that bony union was sound, but this was evidently not the case; he felt that surgeons would soon have unpleasant surprises in certain cases they now regarded as successes. A few fractures of the neck of the femur were impacted abduction fractures, the normal angle between the head and the neck being diminished. Such cases recovered completely with nothing more than rest in bed, and provided that there was undoubted evidence of impaction operative fixation was not required. Of fifty fractures of the usual type seventeen had been operated on two or more years ago with bony union in 60 per cent., and seventeen operated on between one and two years ago showed bony union in more than 80 per cent. This improvement was probably due to improvement in technique, though it was possible that several cases now counted as successes might go wrong later.

Mr. R. WATSON JONES (Liverpool) had formerly been a strong advocate of open-pin fixation, but during the last two years had abandoned it in favour of the blind operation—not so much on the grounds of simplification of technique as on the conviction that the less the fracture site was disturbed by the surgeon the better. The greatest bogy in the treatment of this fracture was necrosis of the femoral head and the arthritic changes that inevitably followed even if union occurred. Necrosis was due to cutting off of the already precarious blood supply to the head, and this could be prevented only by the avoidance of further trauma during the manipulative reduction, by early fixation so that repair could begin as soon as possible, and by keeping clear of the fracture site when the pin was actually inserted. He agreed with Mr. Lloyd's conservative attitude toward impacted abduction fractures.

Mr. H. A. BRITTAIN (Norwich) confessed that his enthusiasm for the Smith-Petersen operation might be an expression of youthful ardour, but what method, he asked, could give comparable results in the hands of surgeons whose experience was limited to not more than fifty cases? His own method (previously described in the *Journal*) had the merit of simplicity, and had given bony union in 82.6 per cent. of his series of forty-six cases.

Mr. K. H. PRIDIE (Bristol) favoured the Hey Groves method. The correct line for insertion of the pin was determined by a guide with two spikes, which perforated the skin over the neck and head of the femur and were pushed in until they made contact with the bone. It had been said that the medial spike might injure the femoral artery, but this fear had been dispelled by a series of post-mortem investigations. He found (by injection of the femoral artery and antero-posterior radiography of the pelvis) that the vessel always lay conveniently medial to the central point of the femoral head. A pneumatic hammer was used to push in the pin, which effectively prevented separation of the neck and head when the pin was passing from the one to the other.

Mr. W. C. GISSANE believed that the operation began with the radiography of the hip. It was most important that comparable views should be obtained from start to finish, and only the surgeon could determine the correct positions for the x-ray tube and the cassette. He, too, favoured the closed method, and employed local anaesthesia, except when the pin was actually being inserted. He did not approve of interference with the compact bone at the point of entry of the pin: a stout rim of bone around the pin enabled him to bury the head under the rim and so prevent extrusion of the pin.

Mr. H. O. CLARKE (Manchester), another advocate of the closed Smith-Petersen operation, gave a detailed report

on a series of twenty cases. Two patients died within twenty-four hours of admission to hospital, the remainder being treated by operation. One died two days after operation, and post-mortem examination revealed advanced myocardial disease; the other died from uraemia three weeks after operation. There was bony union in fifteen cases and non-union in one. In conclusion, he made an eloquent plea for the early transfer of all such cases to a recognized fracture centre. Under modern conditions there was no excuse for attempting to deal with them in imperfect surroundings.

Dr. CARL SEMB (Oslo) also reported a series of 101 cases treated by Sven Johannson's method. He advocated skeletal traction to obtain correct apposition of the fragments, followed by operation at the bedside so that disturbance of the patient, and of the fracture, was reduced to a minimum.

In the afternoon cinema films illustrating some of the techniques employed were shown by Professor SVEN JOHANNSON, Mr. ERIC LLOYD, Mr. PRIDIE, and Mr. BRITTAIN.

SECTION OF OTO-RHINO-LARYNGOLOGY

Wednesday, July 21

Complications of Otitis Media

With the President of the Section, Dr. HENRY HANNA (Belfast), in the chair, a paper was read by Mr. A. A. MCCONNELL (Dublin) on the non-suppurative intracranial complications of otitis media.

Mr. McConnell divided the intracranial complications into suppurative and non-suppurative. The pathology of the former was well understood as each stage in the process had been observed post mortem, but in non-suppurative complications operative findings were often inconclusive and necropsies were rare. He divided the non-suppurative complication into encaphalitic lesions and derangement of the amount, or of the circulation, of the cerebrospinal fluid. The latter led to a rise in the general intracranial pressure. Borries and Symonds had discussed the encephalitic lesion under the terms "otogenous encephalitis" and "non-purulent encephalitis" respectively. It might be the prelude to an abscess of the brain, or at least give rise to the "symptoms of an abscess without abscess." So far as treatment was concerned the case must be treated as one of abscess until negative exploration or subsequent history proved that it was not so. Derangements of the amount of, or of the circulation of, the cerebrospinal fluid were next discussed. The first was described by Symonds as otitic hydrocephalus, using the term to mean an excess of fluid. Outstanding symptoms were intermittent headache and papilloedema. The patient might look extremely well and there were no localizing signs such as were usual in encephalitis. Of great importance was the normal fluid with no excess of protein or of cells. As there was no obstruction to circulation the excess of fluid might be removed at any point in the pathway of the cerebrospinal fluid. The second type of derangement gave rise to collections of fluid localized in the ventricles or in the cisterns of the posterior fossa. They demanded direct removal. Mr. McConnell therefore advocated, in the first type, lumbar puncture as being safe and curative. In the second type it might not be safe and was not curative. As the clinical differentiation of the two types was difficult he suggested ventricular puncture as being a safer and generally applicable procedure.

Otitis Externa

Mr. L. GRAHAM BROWN, in a paper on otitis externa, included all infections of the skin of the meatus or of the skin of the surrounding parts with which it was contiguous. He divided the varieties of lesion into otitis externa circumscripta or furuncle, otitis externa diffusa, otitis externa mycotica or otomycosis, eczematous otitis externa, and otitis externa haemorrhagica. In treatment three main principles were to be observed: (1) thorough cleansing; (2) the application of a non-irritant germicide; and (3) protection from further irritation and infection. He advocated syringing as the safest form of cleansing. The parts could be dehydrated subsequently with alcohol; afterwards he preferred ointments containing zinc. Sulphur and mercury ointments appeared to be too irritating. It was sometimes necessary to give an anaesthetic to exclude other trouble—for example, otitis media deep to the external lesion. Local treatment must not omit the surrounding parts, especially an infected scalp. General treatment included vaccine and serum therapy; manganese and stannoxyl; diet, especially in eczematous patients; light therapy and *x* rays.

Mr. J. W. KILLEN (Londonderry) advocated syringing with a weak solution of lysol. In some eczematous cases he had had much success with resinol ointment, and the general effect of a vitamin A preparation was of value. Mr. T. B. JOBSON (Guildford) agreed about cell sensitivity and advocated the use of calcium in this respect. He wished to say a word about surgical treatment. He had been brought up, as had probably others present, on the crucial incision and curetting of the furuncle. This was now considered dangerous and might spread the infection to surrounding tissues. If any incision were made it should be small and only just sufficient to allow exit of retained pus. Mr. DONALD WATSON (Bradford) divided cases into acute and chronic. He "packed" his cases of boils with aluminium acetate. Like Mr. Killen, he found the cresols useful. Ointments should have a vaseline base, the most effective being salicylic acid and sulphur. He divided chronic cases into those with middle-ear discharge and those without it. The former might need a mastoid operation. Mr. C. DE W. GIBB (Gloucester) found casts in many cases he saw, especially children. Entry of water must be prevented, although patients might think it "dirty" not to wash out the ear with soap and water. He cleaned the ears with olive oil. Re-infection probably often took place by unconscious scratching at night. Mr. DONALD WHEELER said it was most important to see the patient frequently in the early stages. He used "ilon abscess salve," and on dry exfoliative cases liquid paraffin. Mr. KENNEDY HUNTER (Belfast) wished for more information from Mr. Brown about the haemorrhagic cases with a bulla on the tympanic membrance. This often occasioned some deafness, making it difficult to exclude trouble in the middle ear. In furunculosis he advocated tight packing with 8 per cent. aluminium acetate to abort the early case. Mr. J. R. WHEELER (Belfast) recommended prontosil in streptococcal cases. Mr. F. C. W. CAPPS thought that two facts were of importance: (1) the avoidance of surgical incision; and (2) careful personal supervision, preferably in hospital or in a nursing home. An otitis externa might prove far more intractable and painful than an otitis media, and it was wrong to treat such cases as out-patients. No one had mentioned magnesium sulphate paste. He always used it on nicks in the meatus, and it not only alleviated the condition present but prevented subsequent cross-infection of the opposite wall. Ung. hyd. ox. flav. was helpful in the dry and eczematous cases, and also as after-treatment in cases of boils.

The Audiometer

Mr. R. R. WOODS (Dublin), in a paper on the audiometer in clinical otology, said that his work had been done on a Western Electric No. 2B arranged in octaves covering the band from 64 to 8192 cycles per second. The accuracy of this audiometer had never been questioned, but objections had been raised to its application in clinical otology. His paper was mainly directed to the refutation of the conclusion of the Hearing Tests Committee of the Royal Society of Medicine, published in 1933 and apparently condemning the practicability of

the audiometer in clinical practice. By an excellent series of graphs Mr. Woods showed that accurate diagnosis and therapeutic progress could be more easily measured by an audiometer than any other way.

Mr. T. A. CLARKE (Canterbury) congratulated Mr. Woods on his clear exposition of the present uses and future potentialities of the audiometer. He was interested to know if Mr. Woods had found an explanation of the discrepancy between air and bone conduction in the high tones on the monochord. As a member of the Hearing Tests Committee he would defend its attitude. It had met in 1929, and in days of rapid electrical progress its report reflected the opinions of 1929 and not of 1937. It was unfortunate that its report was not published until 1933. Now even the machine used by Mr. Woods was out of date, and he himself, who in 1929 was against the practical use of audiometery, was purchasing the latest model for private and hospital use. Mr. GRAHAM BROWN asked if the instrument was of practical clinical use. If it was they should use it; if not, they should not allow instrument makers to take diagnosis out of their control. Dr. H. C. P. SMITH thought there was an opening for team-work between the otologist, the physicist, and an experimental psychologist. Mr. JOBSON, Mr. KILLEN, Mr. WATSON, and Mrs. BEATRICE H. LYNN (Belfast) also spoke.

Mr. WOODS, in reply, said that the only practical disadvantage he knew was the time the method took. It was no short cut to diagnosis. The discrepancy with tuning-fork findings was a matter of pitch and intensity. Any tone might be heard if it is intense enough. The trouble with aids was the cumbersome nature of those which were efficient.

Tomography

With the President of the Section, Dr. J. C. RANKIN (Belfast), in the chair, the proceedings opened with a paper by Dr. E. W. TWINING (Manchester) on tomography.

Defining tomography Dr. Twining said that it was a means of obtaining clear radiographic definition at a deep plane by blurring of superimposed shadows. This was accomplished by moving the film and the *x*-ray tube during exposure in such a way that the image of object in a selected plane should be held in the same position on the film, while objects on other planes were blurred by the movement. The speaker showed diagrams and a photograph of his apparatus. Tomography not only helped by blurring the details of superimposed structure, but was valuable because it increased contrast. As an illustration an experiment was quoted in which a thick coin was placed at a small distance from the film, and a thinner coin between it and the film. The thin coin was invisible in a normal radiograph, but a tomogram, by blurring the shadow of the thicker coin, revealed the thinner coin, whose edges were well defined because its shadow always fell on the same part of the film. Films were shown demonstrating the value of tomograms in delineating various bony structures. In the spine the tomogram was useful in blurring the superimposed rib shadows in Pott's disease with kyphosis, and in the dorsal spine heart and lung shadows were removed by this means.

There was a rich field for tomography in lung conditions, as had been shown by various workers. The main lines of investigation in the speaker's work had been the demonstration of cavities and the study of the bronchi. Tomography revealed vascular shadows much more clearly than in a normal radiograph. This made it easier to localize certain lesions, and was useful in differential diagnosis, particularly between abscess cavity and peripheral neoplasm. In pulmonary tuberculosis tomography revealed conditions which were often obscure in the normal radiograph. Dr. Twining demonstrated a large number of films of the chest to illustrate the difference between normal radiographs and tomograms.

Dr. A. E. BARCLAY (Oxford) said that the method had great possibilities, particularly in chest conditions. It might also be of great value in the pelvis. Professor JOHN BEATTIE remarked that in his experience of tomography in animals it was not possible to make sections at intervals of less than half an inch, and he found this satisfactory. German tomographic apparatus was very expensive, and he would be glad to know of a cheaper method. Dr. R. MAITLAND BEATH (Belfast) referred to the value of tomography in showing the relation between the symphysis and the sacral promontory. Dr. BARCLAY asked what was the length of exposure and the travel in the tomograms Dr. Twining had shown.

Dr. TWINING, in reply, agreed that tomography was useful in pelvic measurement. Sections at half-inch distances had proved satisfactory in the human subject. The exposure was usually two seconds, and the maximum travel in his apparatus was fourteen inches. He proposed to increase this. For bones a small travel of three to four inches was enough. In answer to a question from Dr. T. G. HARDMAN (Dublin) Dr. Twining explained his method of adjusting his apparatus for different planes by means of diagrams.

Nomogram for Radiography

Dr. A. B. MACLEAN (Glasgow) read a paper on nomogram for radiography. The nomogram was based on Rhinebort's "basic roentgenographic technique," which correlated kilovoltage to the thickness of the part of the body concerned. There were two techniques: that in which current, time, and distance were constant, and the voltage altered according to the thickness of the part; and that in which current, voltage, and distance were constant and the time varied. The data had been obtained from a series of radiographs taken through paraffin-wax phantoms. Dr. MacLean showed a slide of the nomogram, which consisted of three columns: time of exposure, thickness of tissue, and kilovoltage. A standard distance of twenty-seven inches had been used in drawing up the nomogram, but a supplementary table was available for making the necessary correction for other distances. By drawing a line on the nomogram between the kilovoltage used and the thickness, and producing the line as far as the exposure column, the necessary time of exposure was indicated (voltage-thickness technique). The time-thickness technique could also be used if desired. The nomogram had been used in connexion with fifteen machines and applied to them all. It was found that the output of all these machines was the same per milliampere. The nomogram had been devised for bone work, and it was necessary to make corrections in the time or kilovoltage for soft tissues. It had been possible by means of the nomogram to achieve a degree of standardization of technique hitherto unobtainable. Dr. MacLean showed an exposure calculation which translated the nomogram into an easily portable and simple form.

Dr. GRACE BATTEN said that it was difficult to remember so many facts, and she hoped the paper would be published. Dr. C. L. MCDONOGH (Dublin) said that he had received a copy of the nomogram from Dr. MacLean, and that it had worked with uncanny precision. Dr. F. G. GREENWOOD (Blackpool) said he had used the method for two years and had found some difficulties, such as estimating the thickness of the chest wall and in skull work. In ordinary bone work it was very reliable.

Dr. MACLEAN, in reply, said that in order to solve the problem of thickness of chest wall he classified his patients as regards their bulk and made alterations accordingly. Dr. R. E. ROBERTS (Liverpool) referred to the

difference between fat and muscle in such calculation, and doubted whether photographic effect was the same at different voltages.

Radiology in Obstetrics

Dr. C. L. McDONOGH (Dublin), in a paper on radiological diagnosis in obstetrics and gynaecology, said that by radiological means pelvimetry and size of the foetal head could be gauged without anaesthetic or pelvic examination. Diagnosis was rarely possible before the end of the twelfth week of pregnancy. Introduction of gas into the peritoneum to increase contrast was dangerous and unnecessary, but introduction of gas into the colon was often helpful. Radiography was valuable in the diagnosis of hydatidiform mole and of extra-uterine pregnancy. In suspected multiple pregnancy care should be taken to include the whole abdomen in the radiographic field. Radiographic demonstrations of foetal deformity at five to six months might avoid much suffering. In cases of foetal death maceration could be shown early in pregnancy, and, later, Spalding's sign. Injection of opaque material into the uterus before radiological investigation of suspected placenta praevia was dangerous, but uroselectan in the bladder was sometimes helpful. The value of *x*-ray pelvimetry and foetal cephalometry was not yet fully recognized by obstetricians. In the last three groups of Tweedy's classification, where the true conjugate was less than three and a quarter inches, it was useless to proceed to cephalometry, because Caesarean section was inevitable. In Groups 1 and 2 cephalometry was of great value after the thirty-second week because the biparietel diameter increased 0.1 inch per week after that time. If the pelvic measurements were known by pelvimetry the combined information was invaluable. He was certain that eventually every pregnant woman would be subjected to radiographic pelvimetry when first seen.

Dr. R. S. MACHARDY (Portsmouth) said that many obstetricians thought that the taking of radiographs was bad for pregnant women. He had recently investigated the dose received, and had found it so low as to be negligible. Dr. J. F. BRAILSFORD (Birmingham) said that it was a good sign that many wives of medical men were now having radiographic pelvimetry done. Dr. R. E. ROBERTS (Liverpool) said that change of position of the foetus might be very rapid, and caution was therefore needed. Amniography sometimes caused abortion, but not foetal injury. In cephalography there were two factors which could not be determined—amount of movement of the skull bones and force of uterine contraction during labour. A lateral view, including the lumbar region, gave a better idea of the relation of the symphysis to the pelvic brim.

Distance Mass Radiation

Mr. STANFORD CADE demonstrated a cinematograph film illustrating the evolution of distance mass radiation at the Westminster Hospital. The film included details of six mass units used since 1929, and showed their construction and application to patients. The latest unit contained 6 grammes. Accuracy of application, freedom from skin damage, avoidance of effect on general health, and results—particularly in pharyngeal and laryngeal cases—had all become better as the units had been evolved. It was now possible to deliver 9,000 *r* to a pharyngeal tumour at the rate of 9 to 10 *r* per minute without changes in the skin beyond erythema and without blood changes. Radium was becoming cheaper, and this method was therefore more economical than before.

Replying to questions, Mr. CADE said that there had formerly been some cases of delayed cartilage necrosis after treatment of the larynx and pharynx, but this had not occurred for five years. The response of the tumour to treatment was the only criterion, and no reliance was placed on skin erythema. Telangiectasis often occurred in the skin at a later date.

SECTION OF HYGIENE AND PUBLIC HEALTH

Wednesday, July 21

Enteric Fever

With Professor W. J. WILSON, President of the Section, in the chair, the discussion on enteric fever was opened by Dr. JOHN RITCHIE, whose paper was published in last week's *Journal* (p. 160). The subsequent discussion was, in the main, concerned with two aspects of the subject—namely, the practical control and the clinical manifestations and clinical treatment of the enterica.

Dr. S. WATSON SMITH (Bournemouth) ably summarized the clinical signs, methods of differential diagnosis, and the treatment of the disease. His paper was based chiefly upon observations made during the last year's outbreak in the adjacent boroughs of Poole, Bournemouth, and Christchurch. He called attention to the importance of the appearance of enteritis in an area. Such an area might soon be visited by an epidemic of enteric. He emphasized the resemblance of the early cases to acute appendicitis, and stressed the diagnostic importance of Lesieur's sign. In treatment, careful and adequate diet, the prevention of salt depletion, hygiene of the mouth and nose, attention to the fluid balance, were all critically discussed. Serum therapy had given equivocal results in his hands. He believed that serum treatment was the ideal, but that the suitable serum had yet to be found and made readily available. Repeated blood transfusion, perhaps immunotransfusion when possible, was of greatest benefit in haemorrhage or toxaemia, or in a prolonged or relapsing attack of typhoid. Dr. Watson Smith ended with a word on typhoid death, usually believed to result from the myocardium "petering out" from poisoning, but which seemed to him to be due to neuro-circulatory failure, in its turn produced by poisoning of the bulbar centres, similar in many respects to that which caused death in acute pneumonia.

Mr. A. FELIX described recent work upon the antigenic components of typhoid bacilli. He said that two antigenic elements had been shown to be present in therapeutically active sera. These were the O and the Vi elements. The Vi element was of great importance, was extremely labile, and was absent from commercial sera. To be active a serum must contain both of these elements. It was the Vi element which protected against the living organisms.

Dr. S. H. COOKSON (Bournemouth) gave an account of his experiences with the use of Felix serum. He had treated seventy-three patients with it, and believed that the serum was well worth using in all serious cases. He did not employ it as a routine. Lieut.-Colonel C. H. H. HAROLD, discussing water-borne typhoid fever, said that to-day immunity from typhoid depended in large part upon the sanitary methods taken to reduce the number of carriers. In modern life the danger had definitely shifted towards the small rural areas. He believed that the use of the lithium method to prove a connexion between a well and a stream was especially valuable. Dr. C. J. McSWEENEY (Dublin) supported from his further experience the conclusion which he had already published, that the Felix serum treatment was a remedy of real value. Dr. A. GARDNER ROBB (Belfast) remarked that the abolition of 72,000 privy middens in Belfast many years ago had been followed by a remarkable fall in the case incidence of typhoid. But there was a corresponding fall all over the rest of Ulster at that time. Dr. R. J. MAULE HORNE (Poole) made an especial plea for a co-ordinated policy between the local Divisions of the B.M.A. and the local authorities regarding the hospitalization of patients. He believed that hospitalization was necessary in the interests both of the patients and of the community. Dr. GEORGE CHESNEY (Poole) paid a special tribute to the value of Wilson's medium. He described in an interesting fashion the possible sources of infection in the Poole epidemic. Cows

could have infected the milk directly from their teats after walking in the flooded waters of the infected stream. Or it was possible that the community was infected through a cow which died of malignant abortion on August 1. Or, finally, there was the possibility that cows which had become infected were excreting living typhoid bacilli in their stools. All of these points demanded careful inquiry and research. Dr. J. D. ROLLESTON remarked that it was interesting to observe that no clinician had advocated the use of alcohol in treatment.

An interesting paper was presented by Dr. F. MAY ERSKINE (Belfast) on the incidence of goitre in school children in Ulster. The incidence of these cases was related to water supply, to economic position, and to the nearness of the homes to the sea. A higher incidence was universally observed among girls than among boys.

SECTION OF TUBERCULOSIS

Wednesday, July 21

Tuberculosis in Hospital Workers

With the President, Dr. JOHN R. GILLESPIE (Belfast), in the chair, Dr. PETER W. EDWARDS (Market Drayton) opened a discussion on tuberculosis in hospital workers.

Dr. Edwards pointed out that facts concerning the incidence of this disease in hospital workers were still scanty. At the end of this year, however, the Registrar-General would provide the mortality figures among nurses and thus enable comparison to be made with women in other occupations. Investigations had been carried out abroad, and Dr. Edwards referred to those published in Scandinavian countries and in the United States. The incidence had been found higher in nurses than in the general population, and it was generally agreed that it was higher in nurses working in general hospitals than in those working in sanatoria. He thought, too, that far too many "residents" and students in their final years developed the disease. It was insufficiently realized that the personnel of tuberculosis institutions were in the position of true contacts. Prophylactic precautions should therefore be taken by them as by other contacts. The danger of spitting was still inadequately realized. In general hospitals there was much danger from patients, admitted for other conditions, who might be suffering also from pulmonary tuberculosis. Hence every patient should on admission have his sputum, if any, examined for tubercle bacilli, and his chest *x*-rayed. The speaker then dealt in greater detail with the danger in nurses. He deplored the conditions under which they still worked in many institutions. Even a forty-eight hours week was too strenuous for girls during their training, when they also worked for examinations. Once "qualified," they should have the same freedom as women in other occupations. At the sanatorium of which he was in charge the trained staff lived in a hostel outside the institution run entirely by themselves. He stressed the personal hygienic precautions that should be taken during work, particularly the importance of change of clothing immediately on leaving the wards. Tuberculosis in hospital workers should be treated as an industrial disease. Most medical superintendents were in favour of employing staff who had suffered from the disease. Dr. Edwards thought this might prove a better and cheaper solution of an urgent problem than many employment schemes and settlements.

Dr. J. WATT (Godalming) emphasized the possible danger of creating unnecessary alarm in the public mind and of fostering an impression that nursing was a dangerous occupation. He discussed the reasons why tuberculosis should be more common in nurses working in general hospitals than in those working in tuberculosis institutions. There was, however, a real danger of infection in the latter. This danger should be minimized by the teaching and practice of proper hygienic and prophylactic precautions. The general resistance should also be raised by good feeding and avoidance of physical and mental strain. He, like Dr. Edwards before him, thought that at the present time it was not justifiable to exclude tuberculin-negative girls from admission to the nursing profession.

Dr. ESTHER CARLING (*Peppard Common*) stressed the dangers of infection, and particularly of overstrain, in nurses. It was the duty of the medical profession to see that the unfavourable conditions under which girls now train should be altered. She suggested that the matter be taken up by the British Medical Association, working perhaps in conjunction with the Prophit Tuberculosis Trustees and the Joint Tuberculosis Council.

Dr. MADGE MACKLIN (Western Ontario) described conditions in Canada and the results of a questionary which she had sent out. Her remarks gave the impression that Canada was ahead of England in the care taken in choosing girls for training and in the conditions under which nurses worked, and were looked after if they broke down.

Dr. R. MARSHALL (Belfast), speaking from the viewpoint of the general physician, described the experience in Northern Ireland. His investigation, the results of which he gave in full, were based on (1) inquiries from doctors in charge of sick nurses or from matrons of the principal hospitals, and (2) the case-records since 1922 of the Belfast Municipal Sanatorium and the Forster Green Hospital, Belfast. It was certain that almost every nurse who had been diagnosed as suffering from pulmonary tuberculosis in the hospitals of Belfast had been sent to one of these institutions. He concluded that a girl beginning work in a hospital was exposed to a certain risk of tuberculosis. He indicated the precautions that should be taken.

Early Diagnosis of Pulmonary Tuberculosis

The chair was then taken by Mr. J. E. H. ROBERTS, and Dr. GEOFFREY MARSHALL opened the discussion by referring to the difficult position of the general practitioner in connexion with this "troublesome problem." He stressed the fact that a physical examination alone was most unreliable in detecting the early lesions of pulmonary tuberculosis. More fruitful results were, however, obtained when a careful inquiry was made into the past history of the patient, particularly with reference to contact and when pains were taken to elicit symptoms. Such symptoms required careful assessment, since in the earlier stages of the disease they were those of toxaemia and therefore non-specific. One symptom, in the absence of all other evidence, must be considered diagnostic—a free haemoptysis "out of the blue." Dr. Marshall, discussing diagnostic measures, referred to the method of culture on Loewenstein's medium and radiological examination of the chest: "the wise physician will view and discuss these appearances with the radiologist; the wise radiologist will leave the responsibility of diagnosis to the physician." The third important investigation was the diurnal record of the temperature. He finally drew attention to the observation of Wingfield and Macpherson that radiological examination disclosed that about one in every hundred apparently healthy adolescents in factories and workshops had tuberculous lesions in the lungs. He would like to press for the routine periodic *x*-ray examination of nurses, students, and young girls in factories.

Dr. L. S. T. BURRELL stated that what was needed was some method which would indicate the dividing line between mere infection and actual disease. Pulmonary tuberculosis showed itself as an acute, a subacute, or a chronic disease. Examination of the sputum was always of the greatest importance. Absence of tubercle bacilli in sputum that was definitely mucopurulent was highly significant. He strongly recommended the laryngeal test when sputum could not otherwise be obtained for examination. Dr. M. F. O'HEA (Dublin) stressed the impor-

tance of co-operation between the radiologist and physician in interpreting radiographical appearances. The radiologist should always be provided with a full history. It was essential to be familiar with the limits of what constituted a normal film. A period of observation followed by further *x*-ray examination should be practised more often. He showed slides illustrating the radiological diagnosis of "early" lesions in the lung. Dr. J. A. L. JOHNSTON (Londonderry) said that the increase in *x*-ray examinations had exposed the imperfection of the methods of examining the sputum generally used. Many specimens sent for examination were unsatisfactory for this purpose. The physician should be responsible for the collection of suitable specimens. He praised highly the laryngeal mirror test (or merely the use of a slide in a similar manner). The combined gasolene concentration method (as described by Peter Edwards and his co-workers) and culture on a modified Loewenstein medium gave the best results. He thought the subcutaneous tuberculin test dangerous.

The PRESIDENT spoke highly of the value of the subcutaneous tuberculin test. He had carried it out in over a thousand patients and had never seen any disastrous result. Dr. M. ASTON KEY (Southsea) asked how much value should be placed on the pulse rate and on the finding of a small vertical heart in the skiagram. Dr. ANDREW J. MORLAND described a case in which he had found the subcutaneous tuberculin test useful. Mr. J. E. H. ROBERTS stressed the point that other conditions apart from pulmonary tuberculosis might cause a sudden large haemoptysis—for instance, congenital cysts of the lung.

Local News

SCOTLAND

Congress of Medical Women

The fourth congress of the Medical Women's International Association met in Edinburgh from July 13 to 17, and was attended by some 300 delegates from twenty-three countries. This association was inaugurated in New York in 1909, and has held congresses in London, Paris, and Stockholm. The chief scientific subjects discussed at Edinburgh were cancer in women and its prevention, and maternal mortality and abortion, and the meetings were held in the medical buildings of the University. At the inaugural meeting in the McEwan Hall, when Dr. Alma Sundquist of Sweden presided, Sir Thomas Holland, vice-chancellor of the University, in welcoming the delegates, said that they met under a very different mental and spiritual condition from that which Sophia Jex-Blake found sixty-nine years ago. Edinburgh University's association with the development of medical education for women had begun in 1868, when Sophia Jex-Blake tried to gain admission to the University. She and a few kindred spirits were admitted to some classes and not to others, and distinguished themselves in those examinations for which they were permitted to sit, but failed to get the formal recognition necessary to qualify. Four years later in the Court of Appeal the judges decided by a majority that Edinburgh University had exceeded its powers in framing regulations for the admission of women medical undergraduates. Edinburgh thus lost a fine opportunity through the strange ways of the law, and not till twenty years later did the University, under the clearer powers provided by the Act of 1889, frame regulations for the admission of women to medical graduation. Until 1916 it acted purely as an examining body for women students, who received their training outside its walls; this had been partly due to lack of sufficient accommodation. In the last twenty years nearly 600 women medical students had qualified at Edinburgh. Dr. Sundquist, in her inaugural address, said that the association had been founded so that women doctors in all parts of the world might benefit from each other's experience, knowledge, and views. Health was now progressing, the duration of life was increasing, and the death rate was decreasing. Cancer was an important cause of death in women, and large groups of women hesitated, often for too long, before consulting male doctors. Maternal mortality was largely a question of health education, and could in many cases be prevented by suitable advice; women doctors should therefore interest themselves especially in this educational work. At the meeting on July 15 Dr. Simone Laborde, from the Cancer Institute, Paris, said that almost all countries had adopted energetic anti-cancer campaigns. The mortality from cancer had risen in every country during the past ten years, and in Switzerland the incidence of the disease was higher than in any country in Europe. The increase in the death rate from cancer was not due merely to increased longevity. There was no exact evidence that heredity played any important part in its production, but disorders of certain glands with internal secretions might be factors. Special instruction of medical students and doctors was of greater importance at the present time than widespread propaganda, but Toulouse University was the only one which at present had a special chair of "Cancerology." Dr. Elizabeth Hurdon of the Marie Curie Hospital, London, said that the problem of the prevention and cure of cancer was one of the most pressing of our time. In no field of medical research had so much been discovered within recent years. New methods of diagnosis and further advances in treatment were being developed in every part of the world, and in most universities workers were investigating some aspect of the cancer problem. In Great Britain cancer of the breast was the most common form in women, and earlier diagnosis was a matter of vital importance in treatment. There had, however, in the last two decades been a remarkable decrease (21 per cent.) in cancer of the uterus, but theories to account for this change were still speculative. It was known that pure chemical substances applied to the skin could produce cancer in animals, and that cancer of the breast and uterus could be produced by injection of oestrogenic hormones. These discoveries seemed to offer convincing evidence that hormone imbalance was an important contributory factor in the cause of this disease. It was difficult to assess the results of the propaganda regarding early treatment, which had been carried on for some years, and it did not appear, in Great Britain at least, that there had been any improvement in the stage of development at which patients presented themselves for treatment.

A discussion on maternal mortality and abortion was opened on July 16 by Professor Bertha van Hoosen of Loyola University, U.S.A., who said that maternal mortality during the period 1929–34 had increased in Denmark from 32 to 39 per 10,000 of the population, and in England from 43 to 46. In the Netherlands it had decreased from 34 to 32, in Norway from 36 to 29, and in the United States from 70 to 59. In Japan, where high-school girls were taught about maternity, the figures stood unchanged at 28. Abortion was considered a crime in all the English-speaking countries, and in Holland, Sweden, Denmark, New Zealand, and Japan the women were punished as well as the abortionist by imprisonment. In the United States the abortionist was punishable in all States, but the women in Washington only. There were 681,600 abortions annually in the United States, with a death rate of 1.2 per cent., and these occurred chiefly among married women who had had several children. In the subsequent discussion Dr. Rhoda H. B. Adamson (Leeds) said that the question of the general condition of the child-bearing women who died did not seem yet to have been raised. A considerable proportion of mothers who died were women whose health should not have allowed them to have children; these women did not die of child-bearing, which was only the terminal condition.

Dr. Josephine Baker (U.S.A.) said that the high maternal mortality rate in the United States was mainly due to the fact that the midwife was ignored. At the closing meeting on July 17 Miss Louisa Martindale (London) was elected president for the next congress, which is to be held in Budapest in three years. It was decided to continue the discussion on maternal mortality and also to discuss nutrition and venereal disease.

Edinburgh Medical Graduation

At the Edinburgh graduation ceremonial on July 21 Principal Sir Thomas Holland conferred the M.D. degree upon twelve candidates and the degrees of M.B., Ch.B. upon 151 graduands. The honorary degree of LL.D. was conferred upon Dr. Edwin Bramwell, formerly professor of clinical medicine, and in presenting him, Professor H. H. Monteath said that he had inherited from his father, the late Sir Byrom Bramwell, an aptitude for skilful diagnosis and inspiring teaching. He had made peculiarly his own the subjects of encephalitis lethargica with its sequelae and relations, and the different types of myopathy. During his tenure of the chair of clinical medicine and as lecturer on neurology in the University his faculty for clinical exposition had been greatly appreciated, and the esteem and respect in which he was held by his professional brethren had been demonstrated by his election as President of the Royal College of Physicians of Edinburgh. Professor Sydney Smith, in an address on the necessities for change in the medical course, said the study of medicine had been the target for much criticism, and members of the medical profession had been the most ruthless critics. It had been said that medical education was devoid of cultural value, but the aim of any system of education was to build up the mind and character to foster the ability to think, and to cultivate the faculty of appreciation and discrimination. There could be no doubt that for these objects the study of medicine offered as ample a field for thought as any other. There was among the generation of new practitioners an impassioned revolt against the dead hand of the past. Those whom he addressed to-day formed the first group of "war babies" to graduate, and, brought into a world altered out of all recognition, growing up in a spirit of revolt and dissatisfaction, and lacking much of parental control, they had tended to lose faith. The effect could be seen in the modern attempt to find new outlets for intellectual and emotional stress, of which some were intensely interesting, some frankly pathological. This revolt was impossible in connexion with medicine or science, for the course of study did not consist of a chance collection of subjects studied haphazard, but of a carefully considered system built up from a solid foundation. There had been enormous advances in the physical sciences, and a steady but less spectacular progress in the biological sciences and medicine. As a measure of medical effort it might be observed that the mean expectation of life had lengthened by about ten years, the death rate had fallen by 33 per cent., the infantile mortality by 60 per cent., and the death rate from tuberculosis by 64 per cent. Deaths from cholera, plague, malaria, and typhus had practically disappeared from this country, and in the realm of surgery there had been similar advances. All the advances in medicine had had to be incorporated into the curriculum of study without adding to the time taken. This had been done, however, only by very careful adjustment, and naturally there had been difficulties, which continued to grow. The time had now come when an increase in the period of study must occur. The Senatus of Edinburgh University was now deliberating the extension of the course to five full years after the study of the fundamental sciences—that was to say, five years from beginning the study of anatomy and physiology. It was also considering the improvement of the standard of education by endeavouring to keep students at school until the age of 18. This implied the recognition of courses of instruction in chemistry and physics taken at school, and it would allow the study of general scientific subjects to be continued slowly and carefully over a period of years, placing them as subjects of equal cultural importance with others of general education. The advances in human physiology and biochemistry required for efficient teaching a considerable extension in space, equipment, and staff, which must be undertaken by the University in the near future. Many other changes were under consideration, and it was hoped that within a reasonable time it might be possible to provide for students a period of living-in at hospital, where they would be in regular attendance upon their own patients. It was hoped, too, that the dispensary system, which was a unique feature of the Edinburgh school, might be extended so that every student might be brought into personal contact with patients in their own homes, and thus become familiar with the operation of public services for the maintenance of health. A considerable amount of money would be required to give effect to this programme—about £500,000 to do all they wanted in the immediate future.

Glasgow Public Health Services

The Glasgow Public Health Department has issued an attractive pamphlet on "Nursing as a Career for Girls." It sets out carefully the details of training, registration, and conditions of service, as well as the opportunities open to a registered nurse according to her attainments and preferences—private nursing, hospital work with a view to promotion to responsible posts, specialization in such a subject as radiology, the task of nurse-tutor, the nursing services of the Army, Navy, and Air Force, district nursing (a sphere of steadily increasing importance), and municipal midwifery. Stress is laid on the increasing amenities of a nurse's life, the provision in hospitals for recreation, sport, and fellowship, the better adjustment of off-duty times, and, not least, a superannuated retirement. It is even suggested that the training for nursing is advantageous even although it is not intended to adopt the profession as a permanent career, and that nursing is a useful preparation for marriage and motherhood. From first to last there is no reference to Glasgow, but a leaflet is inserted setting out the fourteen hospitals under the administration of Glasgow Corporation and the scope of nursing training which they offer. The second of a series of combined clinics has just been opened by the Glasgow Corporation at Gorbals to serve an area of the city to the south of the Clyde. The building affords accommodation for maternity and child welfare services, education health services, dental and tuberculosis clinics, and a clinic for outdoor medical services in public assistance cases. The outdoor medical services are said to be particularly busy in this area, and four medical consulting rooms have been provided for this purpose. The maternity and child welfare clinic is designed after the most modern principles with a demonstration room for the teaching of mothercraft, a lecture room, and an ante-natal centre. The dental clinic consists of two dental surgeries equipped with up-to-date apparatus. The education health services are given a whole floor, with consulting rooms for general and special examinations, and an orthopaedic department. There is also a small clinic for the treatment of trachoma, a disease which in Glasgow is largely confined to the Gorbals area. The clinic is so designed that the different sections can function separately without interfering with each other. Almost every service has its own special entrance.

Edinburgh Dental Hospital

At the prize-giving of the Edinburgh Dental Hospital and School Lord Salvesen commended to the public an appeal which is now being made for £50,000 to extend the hospital and school. He said that dentistry was one of the few professions which was not likely to be overcrowded in the immediate future, especially if the scheme providing for the periodic examination of the teeth of all school children by a skilled dentist should be carried out.

The Edinburgh school had progressed enormously, and the municipality ought to recognize that it was a source of considerable income to the town as a whole and therefore give it support. It was the largest school of the kind in Scotland, and it had little income from outside sources, depending almost entirely upon the registration fees of the students and gifts which patients in the hospital might make. Lord Salvesen spoke of the great progress in dentistry during his own lifetime. It was of great advantage to health, he said, that people now went to a skilled dentist much earlier, for many diseases which had their origin in decayed teeth could be averted at an early stage but might be difficult to cure later. Poverty was now no excuse for want of dental attention. Mr. A. C. W. Hutchinson, dean of the School, said that necessitous patients came to the dental hospital from all over the south and east of Scotland, and the accommodation was quite inadequate. The governors had accordingly decided that the time had come when the old buildings comprising the back part of the hospital should be pulled down and a modern building erected in their place. The cost had been estimated at over £50,000, and for the greater part of this sum it would be necessary to rely on the generosity of the public. The number of students attending the hospital was now 257, of whom fifty-one were taking a medical in addition to a dental qualification.

ENGLAND AND WALES

Health of London School Children

The report of the School Medical Officer of the London County Council for the year 1936 (P. S. King and Son, Ltd., 14, Great Smith Street, Westminster, S.W.1, price 1s. 6d.) marks continued progress in the state of health of London children. In the last two or three years a new wave of interest and a fresh urge with regard to the children's health have been manifested—anxious concern having been shown for the children's nutritional well-being, for the progress of physical culture, and for improvement in environmental conditions both in and out of school. Considerable progress was made during 1936 in the Council's programme for the improvement and reconditioning of school buildings and equipment, and with schemes for the acquisition of playing fields. Reference is also made in the report to other amenities, such as gymnasia completely equipped and provided with changing rooms supplied with shower-baths, which are being introduced in schools. Close watch continues to be kept on the state of the nutrition of the children. At routine medical examinations of 184,733 children in their age groups a clinical assessment of the state of nutrition was made by the school doctors, assisted by continuous growth charts made by the school nurses, which showed that in 94.01 per cent. of the cases the nutritional state was satisfactory. Of the remaining 5.99 per cent. (comprising 11,057 children whose nutritional state was not wholly satisfactory) only 122 (0.07 per cent.) were found to be suffering from serious malnutrition. In many respects the physical condition of the children was found to be better than ever recorded before, notably in respect of cleanliness, discharging ears, and anaemia. The progress of the nutrition centres established in May, 1935, is recorded, and special attention is directed to this phase of school medical work in London. At these centres patient investigation is undertaken of children who are found by observation in the schools not to be thriving normally. Reference is made to the dramatic results obtained by sending the children to residential open-air schools for a few weeks. The progress of the work of caring for the maladjusted or difficult child is detailed under the heading of "Child Guidance." An account is given of the provision of nursery schools and the care of the infants. Nineteen nursery schools in London are now provided or aided by the Council.

Middlesex Hospital Medical School

At the annual prize-giving ceremony of the Middlesex Hospital Medical School Prince Arthur of Connaught, chairman of the hospital and medical school, presided, and Lord Dawson of Penn presented the prizes and medals to students and nurses. In the course of the proceedings the dean, Dr. H. E. A. Boldero, announced that Mr. Edward Meyerstein had presented to the school a new athletic ground at Chislehurst. Lord Dawson said that this gift would enable the students not only to enjoy recreation but to put themselves in the forefront of a fitter youth. No one needed to be fit more than did doctors and nurses. Medicine demanded the hardest work and gave the fullest life of any calling in the world. Their minds could never be dull in medicine, because they lived in a land of knowledge in which they were always trying to add something from the uncharted land all round. The ancillary services, of which the exponents in the Middlesex Hospital Medical School were outstanding in repute, were an invaluable aid, but they must be careful to hold the balance between those services and clinical medicine. The dean also reported that the medical school had received from an anonymous donor a sum to create a "Rudyard Kipling Fund" for helping students or recently qualified Middlesex men who might otherwise have to abandon a medical career. Dr. George E. Beaumont, physician to the hospital, delivered the introductory address, the title being "The Breath of Life."

Bournemouth's Sanatorium Hospital in the New Forest

Bournemouth recently acquired the private institution at Linford in the New Forest which had been carried on for a number of years by Dr. A. de W. Snowden. The corporation's plans provide for the erection on the site, which extends to 125 acres, of a modern well-equipped sanatorium hospital to accommodate at the beginning 100 or 120 beds. For the present the existing provision for about thirty patients is being utilized, the first patients having been admitted on May 1 last. When completed the new institution will afford accommodation and treatment for all types of cases—early, intermediate, and advanced. Linford is two miles from Ringwood off the Romsey Road, and fourteen miles from the Square, Bournemouth. The sanatorium will thus be situated in some of the loveliest country in the south of England, and its position on a slope facing south-east with protection from the north-east and south-west will make it ideal summer and winter for the purpose for which it is intended.

South-Eastern Regional Committee on the Deaf-Blind

The South-Eastern Regional Committee on the Deaf-Blind publishes a report of the preliminary survey undertaken during 1936 of the problem presented by the deaf-blind in London and the South-Eastern Counties. The proportion of blind persons in this area who are also deaf is stated to be approximately 6 per cent., representing a total of roughly 1,110 deaf-blind persons. The grey existence of these doubly afflicted people, whose lives are necessarily painfully isolated, can be lightened by friendly visitors of the right type, especially those with some knowledge of the psychology of the deaf, or, preferably, of the deaf-blind. For such visitors extreme patience and a capacity for listening are the most desirable qualities. The report also points out the need for correlating the functions of whole-time, part-time, and voluntary workers and the work of general administration. The desirability of the careful examination of the deaf-blind by aural specialists is also stressed, followed by a thorough trial of types of aids to hearing. It is further suggested that cases of defective hearing among the blind should be systematically examined as early as possible with a view to preventing, or at least delaying, the onset of more advanced deafness. Copies of the report are obtainable from the joint secretaries at 66, Victoria Street, S.W.1, and 96, Bramfield Road, S.W.11

Correspondence

The Abuse of Caesarean Section

SIR,—After an experience of examining during many years I am appalled by the increasing tendency for students to answer any question on complicated labour by the simple formula "Do a Caesarean section." Recently a question on a transverse lie with a prolapsed arm was answered by many of the candidates in the same way, some emphasizing that this should only be done if the uterus was in tonic contraction and version could not be carried out.

Now if Caesarean section was a really difficult operation like Wertheim's hysterectomy, I should not be worried, knowing that it would not be attempted; but it is the simplicity of the Caesarean operation that makes it so dangerous. That there are thousands of unnecessary Caesareans performed is serious enough in itself since it raises the risk of death to the patient from 4 per 1,000 to 1 per cent., but when it is carried out as a last resource the risk to the mother is appalling. We teachers of midwifery must realize our responsibility in discussing Caesarean section with students.—I am, etc.,

London, W.1, July 23. MALCOLM DONALDSON.

Anaesthesia in General Practice

SIR,—I was interested to read Dr. Helen Lukis's article on the choice of anaesthetic in general practice in the *Journal* of July 17 (p. 126). I have been in general practice for nearly fifteen years, and I have given altogether 8,900 anaesthetics, of which rather more than 1,000 were administered before I qualified. I should like to make a few observations on the subject. First, with regard to avertin, I have found this drug to be ideal as a pre-anaesthetic medication when it is not given in doses sufficient to produce surgical anaesthesia, and I think Dr. Lukis has magnified the disadvantages attending its use. May I take these seriatim from her article?

In the first place, I think anaesthetists are now generally agreed that avertin should be used only as a pre-anaesthetic drug, and that when used in this way it is usually safe, except in cases in which it is obviously contraindicated. In the second place, the 500 c.cm. and 10 c.cm. measuring cylinders, glass flask, and thermometer can all be kept in an ordinary cupboard or on a shelf in a dispensary, and with care they are not more breakable than other glass apparatus. Thirdly, the dosage table provided by Bayer and Co. is perfectly simple and reliable, since it gives the quantity of distilled water and avertin fluid required for any given weight.

I always make up the solution at home at any convenient time within two hours of its intended administration. This time limit was given to me by a very well-known London anaesthetist, who was one of the first to use the drug in this country, and who has used it extensively since its introduction. It takes me about ten minutes to make it up, put it in a vacuum flask, and put away the apparatus. I will admit that until I was familiar with the routine I took a full twenty minutes. If the patient is a child I then take the flask to the nursing home, and leave it for administration by the nurse half an hour before the time of operation. Any recently qualified nurse is familiar with the drug, and even if she is not it is a very simple matter to run about 225 c.cm. of fluid from a vacuum flask into the rectum by means of a No. 10 or No. 12 catheter, a tube, and a funnel. If the patient is an adult I see him first and give it myself, so that he does know that I have in fact been present. This would be particularly desirable just now in case the patient had lately read Dr. Cronin's latest novel.

Lastly, with an ordinary Centigrade thermometer in a rubber stopper in the flask used for heating the water it is quite simple to ensure heating to the proper temperature; and in case this is forgotten it is noted on the dosage table already mentioned. I completely fail to see that avertin is a "very dangerous weapon in the hands of the family doctor" provided that a little trouble is taken in becoming familiar with the necessary procedures.

Dr. Lukis again, I think, is hardly fair to gas and oxygen, which, as everyone agrees, is by far the safest inhalation anaesthetic we possess. With two fifty-gallon cylinders of nitrous oxide and an oxygen cylinder there is ample material for at least two long major operations, especially if avertin has been given first; and it is possible nowadays to get really portable apparatus, such as a "Boyle's bottles" unit with a sight-feed bottle instead of flowmeters. This is not prohibitive in price nor difficult to keep in good working order. Admittedly, the whole apparatus is less portable than a bag containing a mask, a bottle of chloroform, and a bottle of ether, but the extra time and trouble taken are well worth while in avoiding the post-anaesthetic effects of chloroform and ether.

Another point to bear in mind is that in these enlightened times, when the medical profession is unfortunately not enjoying a "good press," the average intelligent layman knows almost as much about recent advances in medical knowledge as we do ourselves; and when he reads in his morning paper a glowing account of some wonderful drug or appliance which makes anaesthesia pleasant and easy, it behoves us, as family doctors, to be conversant with it; and, moreover, he will certainly expect us to be so! I find that during the last year or two an increasing number of patients are actually asking to have avertin given to them if they have to undergo an operation.—I am, etc.,

Coulsdon, Surrey, July 23. R. B. P. LANSDOWN, M.B., B.Ch.

Hermaphroditism

SIR,—In the light of Mr. H. Chapple's recent article on hermaphroditism (*Journal*, April 17, p. 802), a case which came under my care at the Royal Hospital, Richmond, some years ago might be of interest.

A woman, aged about 32, was sent to me with a diagnosis of "imperfect vagina." She was well developed, of average height and with normal breasts. Moreover, she was anxious to have a child, although she had never menstruated nor experienced sexual desire. On examination the external genitals were found to be normal, the vagina being about three inches long, but no cervix or uterus could be felt. I communicated with the patient's doctor, and left the matter in his hands. About four weeks later the woman was admitted to the hospital suffering from appendicitis. In the course of the operation the following extraordinary condition was made manifest.

The uterine body was represented in the mid-line by a small round nodule one-third of an inch in diameter. From either side of this structure two solid, rounded, elongated bands of tissue, looking like uterine muscle, stretched out round the pelvic brim. These bands gradually increased in diameter to about one and a quarter inches at the distal end. Fastened on to each end was a large glistening white structure which I took for unusually large ovaries. Along the outer side of each of these was a minute tubule, ending in two or three tiny strands of fimbriae of the Fallopian tube. There was

attached to each a small mobile cyst of Morgagni. The round ligaments were three-eighths of an inch in diameter continuous with the bifurcated uterine bodies and passing to each internal abdominal ring.

It appeared as if a bicornuate or didelphys uterus had been intended by Nature. Pathological examination showed that the elongated structures were composed of uterine muscle, both white bodies were normal testicles, and the tubules were vestigial Fallopian tubes without cilia.—I am, etc.,

Richmond, Surrey, July 24. JOHN W. HEEKES.

Tests for Renal Function

SIR,—I read Dr. C. S. D. Don's article on tests for renal function (*Journal*, July 10, p. 54) and his conclusions with interest. Dr. Don suggests that the different methods in use may test different renal functions, and in part I believe this to be true. During the last two and a half years I have been engaged in an investigation of the renal state in regard to the disorders of pregnancy and the puerperium, using both the urea clearance test and the older "concentration factor" test. I have used this older method because I am convinced of its value in the assessment of renal damage when the later test alone will fail to find it on account of an existing compensatory diuresis.

In a series of about seventy normal pregnant women the concentration factor has always been the normal 50 or more under standard conditions, the clearance well over 70 per cent. I have therefore assumed that in cases of pregnancy toxaemia of the various types a low concentration factor has indicated renal damage—according to the established view that one of the first signs of renal damage is impairment of this concentrating power—even when the clearance has been normal or over. This accords well with the known flexibility of renal function as expressed, for example, by Fishberg: "The factor of safety of the kidney is so great, its compensatory mechanisms of such great moment, that these changes [disturbances of renal function] are often far from obvious. I have come to believe that the concentration factor, though merely a test of the concentrating function of the kidney, is of value in indicating existing damage, and that the urea clearance test, a test of nitrogenous excretion, is of particular value in estimating the degree of compensation present.—I am, etc.,

Leeds Maternity Hospital, July 24. NORMAN LISSIMORE.

When to Operate in Appendicitis

SIR,—Mr. R. J. McNeill Love's statement that a circumscribed swelling in the right iliac fossa in association with acute appendicitis is an abscess (*Journal*, July 24, p. 184) requires some qualification, particularly as it is a criterion of operability to the exponents of the Ochsner-Sherren treatment; in some cases that I have operated on the "circumscribed swelling" palpated before operation has proved to be either a mass of inflamed omentum or an indurated caecum. It has not been my experience that in three months after the acute attack has subsided "freedom from adhesions is remarkable"; in those cases in which the conservative method has been followed I find that a six-months interval is nearer the mark.

Further, that "efficient expectant treatment can only be carried out in a nursing home or hospital where the patient is under constant supervision of the surgeon" is a statement vitiated by its ending. If the Ochsner-Sherren treatment is so good surely the family doctor is capable of carrying it out and evaluating the signs which call for its abandonment. Surely it is a simple matter for the surgeon to open an appendix abscess in the patient's home. After all, an operating theatre is just four walls and a roof; it's the technique that matters.—I am, etc.,

R. RUTHERFORD, F.R.C.S.

Longtown, Cumberland, July 24.

Defective Hearing

SIR,—May I reply to Mr. A. Lowndes Yates's criticism (July 10, p. 90) of my article published in the *Journal* of July 3 (p. 18), and to that of Dr. James Kerr in the issue of July 17 (p. 135).

The ordinary conversational voice, as everyone knows, cannot be standardized. The response to this test varies according to the voice of the individual who is conducting the test, quite apart from environmental conditions; but it is possible for anyone engaged in frequent testing to develop a fairly constant "ordinary conversational voice" for the purpose required, and thus create a rough standard for this test.

I quite agree with Mr. Lowndes Yates that all these tests—the ordinary conversational voice, the pure tone audiometer, and the gramophone audiometer, etc.—should be conducted in a silent place, but unfortunately this is not universally possible at present. For example, the gramophone audiometer tests of school children must be conducted under ordinary class-room conditions. Accordingly, the ordinary conversational voice tests and the pure tone audiometer tests are conducted as nearly as possible under similar conditions, although in the pure tone test the meatus of the ear that is not being tested is occluded. As a matter of practical experience, with my own "ordinary conversational voice" and under the conditions stated, I find that a child who can repeat unfamiliar phrases at not more than twenty feet distant gives a loss of about 35 decibels over the main speech area (512–2,048 d.v.). With better conversational hearing than twenty feet the loss by the pure tone audiometer test shows something less than 35 decibels. Further, with conversational hearing at two feet only the pure tone audiometer test shows a loss of about 55 decibels over the main speech area. I have found in a considerable number of tests that this relationship between the response to the ordinary conversational voice and the pure tone audiometer is remarkably constant, and these two levels of hearing response form my boundaries between Grade I and Grade II in the first instance, and between Grade II and Grade III in the second, so far as the hearing qualification is concerned.

Mr. Lowndes Yates says, "If we assume that the ordinary conversational voice can be heard at a maximum of fifty feet, to hear at twenty feet shows a diminution of hearing power of about 6 decibels, but we are also told that the hearing loss with the pure tone audiometer is 35 decibels in this grade." I do not know why he assumes that the ordinary conversational voice can be heard at a maximum of fifty feet only. Harvey Fletcher has made careful investigations on this point and finds that the ordinary conversational voice can be heard at 1,250 feet. Mr. Lowndes Yates correctly says that a loss of 35 decibels with the pure tone audiometer means that the hearing distance is diminished to about one-fiftieth of the normal. One-fiftieth of 1,250 feet is 25 feet, which is surely getting very near to my own figure of 20 feet, and "about one-fiftieth" (his own words) might even bring it to exactly that figure.

With regard to the letter of Dr. James Kerr, who has always taken such a great interest in the welfare of the deaf, I agree that the number of persons coming within the scope of a Deaf Persons Act would be determined by the restrictions of such an Act. It seems to me, however, that an Act should not only embrace the 30,000 so-called "deaf and dumb" but also those severely deafened persons who would suffer from extreme handicap in their struggle for existence in competition with their more normal fellows—in short, those whose hearing defect is covered by my Grades IIb and III. The great difficulty is to get an accurate idea of this number.

My object was to estimate an outside figure within which this number would probably fall, so that the full nature of the problem would be indicated and a basis for further consideration arrived at. If an Act contained restrictions limiting its benefits only to the persons of Grade III type and to the more seriously deafened in Grade IIb, my outside figure of 150,000 would certainly be reduced to well under 100,000, but I consider an Act which covered only the 30,000 "deaf and dumb" in the country, while better than nothing, would not meet the needs of all the severely deafened and handicapped people. —I am, etc.,

Medmenham, Bucks, July 20. ARTHUR G. WELLS.

Ionization for Hay Fever

SIR,—I feel that there are one or two points in Dr. J. Adam's letter in the *Journal* of July 10 (p. 88) which cannot pass without comment.

First, he says that "some fibrinous exudate is troublesome for the first few days after treatment, but it is probably this and weakened ciliary action that explains the benefit." Now surely zinc ionization produces a protective film of zinc albuminate, thus limiting the absorption of the pollen proteins by the nasal mucosa. We know, too, that the most important function of the ciliary stream is the removal of mucus-entangled bacteria, dust, pollen, etc.; and that prolonged contact of these substances with the allergic mucosa serves to increase its sensitivity towards the specific allergen. Yet Dr. Adam would appear to suggest that weakened ciliary action plays a part in the beneficial effects of ionization.

Again, he says that "American writers have imputed ciliary damage to ionization. Such damage I have not seen, though it may conceivably happen from over-treatment." A study of the pathology of hay fever will show that metaplasia of the epithelial cells in varying degree, with replacement of the columnar cells by stratified cells and absence of cilia, is a constant feature in hay fever. So, while I agree with Dr. Adam that it is wrong to attribute permanent ciliary damage to ionization, except possibly as the result of over-treatment—or, more probably, the passage of too strong a current for too long a time in the presence of too strong a solution of zinc sulphate—I find it a little difficult to picture the nose of the medical patient referred to by him as being "quite normal" when "he returned for treatment before the beginning of this season."

Lastly, I cannot agree with him as to ionization being "mostly futile" for paroxysmal rhinorrhoea. It has been my experience, and apparently the experience of the vast majority of British and American writers, that ionization is of greater benefit for paroxysmal rhinorrhoea than for hay fever, but that in both cases its value is definitely palliative and very rarely curative.—I am, etc.,

Bath, July 20. C. A. HUTCHINSON.

Colitis in Mental Hospitals

SIR,—Relating to the discussion on the surgery of the colon initiated by Mr. Eric Crook at the Royal Society of Medicine (*Journal*, May 29, p. 1129), may I add the following remarks? Forty years ago colitis used to be the scourge of the London workhouse infirmaries, whence the mental patients were sent to the London asylums, and in these institutions the disease often spread with many fatal cases. In my experience at the opening of the new and clean Claybury Asylum in 1893—the first asylum of the first London County Council—many hundreds of its insane population were received from the overcrowded Poor Law infirmaries, and some of these people were suffering from colitis with diarrhoea and the passing of blood and mucus. The disease often spread to others occupying beds adjoining them in the dormitories, so that its occurrence came to be regarded as a discredit, indeed as a disgrace, to the administration. In order to emphasize the reproach the term dysentery, implying infection and want of care, was applied to all cases of colitis, and every case had to be reported to the pathologist. The seriousness of colitis—now called dysentery—was shortly afterwards recognized by the Board of Control (Lunacy Commissioners), which instructed that every case of colitis (now asylum dysentery) occurring in the asylums of England and Wales (now mental hospitals) should be reported to the Board and described as dysentery.

In the London County Council report of the asylums committee for 1914 my personal experience at Claybury is recorded with that of others. Dysentery (colitis) then occurred in 125 males and 286 females in the asylums of London, which had a population of about 20,000 insane persons. The pathologist, Sir F. W. Mott, added, "The cases for the most part have occurred in groups of two or more in the same ward." In the report of the Board of Control for 1935, 450 fresh cases of dysentery are reported in the mental hospitals of England and Wales, and the incidence is quoted as 3.6 per 1,000 patients.—I am, etc.,

London, W.8, July 23. ROBERT ARMSTRONG-JONES, M.D., F.R.C.P.

Birth by the Rectum

SIR,—I was interested in Dr. J. B. Patel's report of a birth by the rectum (*Journal*, June 5, p. 1159), as I had a similar case in December, 1936.

A young unmarried Kikuyu woman was brought into the native hospital at Fort Hall. She had given birth to a still-born child through the rectum about three days previously and was complaining of constipation. On examination, the whole of the vulva and perineum were covered with keloid growths about the size of large acorns. This was the result of an old circumcision scar, it being the habit of the Kikuyu to circumcise their young women, often with a resultant traumatic atresia of the vaginal orifice, which necessitates operative intervention before they can deliver their first babies. The vaginal orifice was fibrosed and would only admit the second finger with difficulty. I discovered that the child had been delivered through the posterior vaginal wall and then through the anterior wall of the rectum. These had probably been torn, as a result of the force of the labour pains and of the child escaping along the line of least resistance. The perineum itself was intact. On arrival at the hospital the woman was already in a septic condition and died from puerperal sepsis three days later.

I was surprised that the perineum was not lacerated, although the sphincter ani was; but when the large size of the stools that these natives sometimes excrete en

defaecation are considered it can be understood why the perineum was not injured in this case.—I am, etc.,

P. G. PRESTON, M.B., Ch.B., M.C.O.G.

Kenya Colony, July 12.

Treatment of Retained Placenta

SIR,—I was much interested in Mr. David Currie's article in the issue of July 10 (p. 57), because for nearly twenty years I have injected the cord as a routine in all cases of uncomplicated delay in the third stage of labour. In fact so anxious have I been to avoid manual removal that in many cases injection has been repeated as many as three or four times over a period of hours, usually even then with success. Furthermore, in cases sent into hospital hours after delivery this procedure has almost invariably succeeded.

My technique is simpler than that which Mr. Currie describes largely because I have never tied the maternal end of the cord except, of course, in cases of multiple pregnancy. I gather from his paper that he always ties this end. I maintain that an "empty" placenta will come away with greater ease than one in which the cord is ligatured. Tying of it will cause it to be engorged and bulky. I entirely agree with Mr. Currie as to the probable mechanism of separation, etc., following injection, and therefore, since this is largely due to increased bulk after injection, why not start with as empty a placenta as possible and make the contrast as a result of filling it with fluid even greater? Further, a cord empty of blood is easier to inject as it contains practically no clots. Space will not permit me to go into my technique in detail, but I feel that for simplicity it can hardly be bettered.

Very briefly it is: leave the maternal end of the cord untied; freshen it by cutting off the terminal inch or so; use a rather fine-pointed glass Higginson's nozzle (with a Higginson's syringe) the end of which is slightly bulbous. This latter enables a ligature to be used to tie the cord over the nozzle. As a matter of fact this is seldom necessary as a firm grip with the gloved hand is all that is required to make a watertight "joint" between the cord and the nozzle.

I may add that during these twenty years manual removal has had to be performed by me on five occasions both in private and in hospital work. This figure does not, of course, include cases other than those at or near term.—I am, etc.,

J. R. CAMPBELL CANNEY.

Cambridge, July 19.

The London Fever Hospital

SIR,—Medical practitioners who know and use the London Fever Hospital will welcome a recent decision of the Committee of Management to extend the isolation accommodation.

A contract has been signed for the erection of a new three-storied building providing single rooms on two floors, with an operating theatre, and small wards for children above. The architects are Sir Aston Webb and Son, and the design carries out in their entirety the recommendations of the Medical Committee. There are balconies to all floors, running completely round the building, and all nursing and service will be from the open air without internal corridors of any sort. An appeal will be launched in the autumn, and we shall be grateful for all the help we can get. We hope, too, that all who are interested will see the new building in due course, and in the meantime we commend the service of this hospital to our colleagues in the Greater London area. Private rooms are available for paying patients, and a high standard of nursing and maintenance can be relied upon.

This was the first, and it remains the only, voluntary fever hospital. Its growth and endurance through 135 years of service and its importance in medical history give the hospital an honoured place in the voluntary system.—We are, etc.,

CHARLES R. BOX, M.D., F.R.C.P.
JOHN F. H. BROADBENT, M.D., F.R.C.P.
WILLIAM H. WILLCOX, M.D., F.R.C.P.
C. E. LAKIN, M.D., F.R.C.P.
C. W. GORDON BRYAN, F.R.C.S.
D. F. A. NEILSON, F.R.C.S.
THOMAS HUNT, D.M., F.R.C.P.
K. SHIRLEY SMITH, M.D., F.R.C.P.

Obituary

Dr. HORATIO E. RAWLINGS died at Bishopston, Gower, on July 15. The son of a Wesleyan Minister, he was born at Sunderland in 1859 and went to Swansea at an early age. He studied medicine at Queen's Hospital, Birmingham, and the London Hospital, and graduated L.R.C.P.I. in 1887 and M.R.C.S.Eng. in 1889. Following a period as house-surgeon at the Swansea General Hospital he began private practice in the town, but soon went to Reynoldston, Gower, where he worked for several years. In 1903 he returned to Swansea, and soon built up a large private and insurance practice; for many years he was medical officer to the Swansea Post Office. Dr. Rawlings was chairman of the Swansea Division of the British Medical Association in 1923–4. He took a keen interest in sport, and was medical officer to the Swansea Rugby team for a number of years. He was a clever and keen musician, and acted as organist and choirmaster to the Brunswick Church for a period of twenty-five years. He was conscientious, modest, and generous as a doctor, a true and devoted Christian, and in maintaining the highest traditions of a general medical practitioner endeared himself to his patients and to the general public of Swansea. He is survived by a widow and seven grown-up children.

We regret to announce that Dr. JOHN ANDREW CLARKE of Luton died in London on July 4 after an operation. The eldest of four sons, who all joined the medical profession, he was born in 1868 and studied at Queen's College, Galway, and Belfast, graduating B.A. of the Royal University of Ireland in 1906 and taking the M.B., B.Ch. and B.A.O. degrees in 1909. He began practice at Luton in 1922 and joined the Bedfordshire Branch of the British Medical Association, and was appointed medical officer to the East Ward, Luton, and public vaccinator for the East District. He had been a member of the Bedfordshire Panel Committee, and served on the committee of the Luton Medical Society. He leaves a widow, two sons, and two daughters; the elder son, Dr. J. R. G. Clarke, was in partnership with his father, and the younger son is a medical student at Oxford. Dr. J. A. Clarke's death from pulmonary embolism following an operation for acute appendicitis has come as a great shock to his many friends and colleagues in Luton and its neighbourhood.

The following well-known foreign medical men have recently died: Dr. FÉLIX DE LA LAPERSONNE, formerly professor of ophthalmology in the Paris faculty of medicine and president of the Académie de Médecine and of the International League for the Prophylaxis of Blindness; Professor MARIO CARRARA, successor to Professor C. Lombroso in the chair of criminal anthropology at Turin, and editor of the Italian Archives of Criminal Anthropology founded by Lombroso.

Universities and Colleges

UNIVERSITY OF OXFORD

H. M. Sinclair, B.Sc., B.M., M.A., has been elected to an official fellowship and tutorship in physiology at Magdalen College.

E. H. Leach, B.Sc., M.A., has been appointed to a lectureship in physiology at Brasenose College.

UNIVERSITY OF LONDON

At a meeting of the Senate held on July 21 the title of Professor of Morbid Anatomy in the University was conferred on G. R. Cameron, D.Sc., M.B., B.S.Melbourne, in respect of the post held by him at University College Hospital Medical School. The D.Sc. in Applied Physiology was conferred on G. P. Crowden, M.R.C.S., L.R.C.P., University Reader at the London School of Hygiene and Tropical Medicine.

The following candidates have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN BACTERIOLOGY.—H. Berry, C. T. Calam, S. P. Gupta, T. Richards, Phyllis M. Rountree, N. K. Sen.

ACADEMIC POSTGRADUATE DIPLOMA IN PSYCHOLOGY.—T. M. Anklesaria, Dorothy L. Burch, Carla B. Freeman, Margaret E. Gurney, Edna Howard, Christina M. Hueffer, Pamela Middleton, K. L. Parker, J. L. Peterson, Ethel M. Turner, Jean A. Wales, Z. Wonchockier, Lola M. Woods.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

The following scholarships, exhibitions, and prizes have been awarded at University College Hospital Medical School: *Goldsmid Entrance Scholarship*, R. E. O. Williams, Stella D. Morton. *Goldsmid Entrance Exhibition*, E. Petrie. *Atchison Scholarship*, L. J. Honeywill. *Atkinson Morley Scholarship* and *Magrath Scholarship*, A. S. Aldis. *Filliter Exhibition*, Isabel T. Hinde. *Fellowes Gold Medal*, A. M. Barry. *Fellowes Silver Medals*; P. H. Wood, D. A. Ferguson, Elizabeth Topley. *Liston Gold Medals*, *Alexander Bruce Gold Medal*, and *Tuke Silver Medal*, J. D. N. Nabarro. *Tuke Bronze Medal*, W. M. L. Turner. *Junior Clinical Surgery Prizes*, R. N. Houlding, M. F. Pilcher. *Ferriere Scholarship*, Ivy Tuck. *Bilton Pollard Fellowship*, M. Coleman, M.S., F.R.C.S.

LONDON HOSPITAL MEDICAL COLLEGE

The Price University Scholarship in the subjects of anatomy and physiology, value £100, open to students of the Universities of Oxford and Cambridge, has been awarded to P. W. Roe of Wadham College, Oxford.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The following awards of scholarships for 1937–8 are announced:

St. Dunstan's Exhibition: A. M. Dealler. *A. M. Bird Entrance Scholarship*: J. Myers. *Mabel Sharman Crawford Scholarship*: E. M. Robson. *Mrs. George M. Smith Scholarship*: V. J. McMullen. *MacIntyre Evans Scholarship*: L. M. Chant. *School Jubilee Bursary*: Mrs. E. Skelsey. Dr. *Margaret Todd Scholarship*: B. C. Mulvany. *Sarah Holborn Scholarship*: J. S. Davis. *A. M. Bird Scholarship for Clinical Studies*: B. J. H. Broadwood. *Alfred Langton Scholarship*: R. E. M. Bowden. *Ellen Walker Bursary*: M. Westmoreland-White. *Flora Murray Bursary*: E. Broadhead. *Beilby Bursary*: A. J. Blayn and E. A. Kaye. *Special Scholarships and Bursaries*: M. S. Cam, J. M. Drury-White, V. E. A. Sykes, M. L. Taylor, and M. V. Teichmann. *A. M. Bird Postgraduate Scholarship in Pathology*: M. Barber. *Mabel Webb and A. M. Bird Research Scholarship*: Marjorie V. N. Sudds, M.B., B.S., D.T.M. and H.

UNIVERSITY OF MANCHESTER

The Professor Tom Jones Memorial Surgical Fellowship has been awarded to T. S. B. Kelly, and Entrance Scholarships in Medicine to A. N. Guthkelch and L. Wise.

UNIVERSITY OF EDINBURGH

A graduation ceremony was held in M'Ewan Hall on July 21. The following degrees and diplomas were conferred:

HON. LL.D.—Edwin Bramwell, M.D., F.R.C.P., formerly Professor of Clinical Medicine and President of the Royal College of Physicians of Edinburgh.

M.D.—**W. M. Arnott, *F. Ayrey, J. C. Caird, *A. F. Cowan, R. W. Eason, **A. Haddow, **T. N. MacGregor, *H. M. D. Shepherd, J. K. Slater, I. D. Sutherland, **R. Walmsley, A. M. Watt.

M.B., CH.B.—J. Adelmann, G. O. Airey, L. Altman, J. P. Baird, H. A. Barker, Barbara U. Barnetson, M. R. J. Behrendt, H. J. Bell, D. K. Binder, Isabella R. Bishop, T. M'K. Boog-Scott, C. H. Bosenberg, S. O. Bramwell, T. J. Brownlee, K. I. Bruce, Jean M'K. Brunton, J. E. Buck, A. G. S. Calder, E. Campbell, D. L. Carmichael, C. Chesner, R. S. Churchward, G. J. Cleland, Joan K. Cunningham, Margaret H. Darling, †J. N. Davidson, S. Davison, B. Diamond, J. Dolgin, C. A. P. Donaldson, E. M. Donaldson, J. K. Drummond, D. E. Durran, Louise F. W. Eickhoff, †J. R. Frank, J. W. Fraser, Helen M. Gardner, S. Gellis, A. M. George, †A. D. Gillanders, R. O. Gillhespy, A. Graham, L. A. Griffith, C. Groves, J. Guthrie, R. H. Hannah, P. W. Hannay, E. I. B. Harvey, J. W. Heath, A. J. Hogan, R. W. B. Holland, G. Hollingsworth, J. Hotson, H. G. H. Houghton, Sir Eric O. A. Hutchison, J. E. Hutton-Mills, †J. Innes, J. C. J. Ives, W. O. James, †R. A. Jamieson, H. C. Jeffrey, R. W. P. Johnson, P. K. Kaufman, G. A. Kelsall, W. G. Kerr, H. M'P. Kilgour, F. Lake, F. W. Laurie, Deirdre M. Lewis, Elizabeth I. Low, R. B. Lucas M. Ludlam, Elizabeth M'Callum, Henrietta R. M'Cree, W. L. MacDonald, G. D. M'Dowall, A. A. MacGibbon, W. MacGregor, G. D. M'Intosh, R. A. M'Kail, J. M'Kee, A. M'Kelvie, D. H. MacKenzie, Agnes P. M'Laren, J. A. M'Laren, I. A. M. Macleod, W. Macleod, I. Macphail, D. A. Macpherson, R. L. Macpherson, Sheila M. L. M'William, V. S. Magnus, G. D. Malcolm, Joy I. G. Matson, H. J. S. Matthew, H. Meyer, J. Millar, J. H. Milligan, J. C. Milne, H. Milne-Redhead, A. Mondal, L. G. Morrison, A. J. G. Newton, W. Noordenbos, P. T. Northover, R. K. Oag, H. T. Osmond, M. W. Paterson, N. Pederson, D. B. Peterkin, G. J. Phillip, A. M. Phillips, L. Pollack, A. C. Reid, †F. H. Robarts, Ethel E. Robertson, R. P. Robertson, H. D. Rosenberg, W. Rosenbloom, D. C. Ross, G. I. M. Ross, J. M. H. Ross, J. M. Ross, R. M. Ross, A. P. Russell, K. D. Salzmann, D. L. Savill, G. W. Senter, A. C. Shrelford, J. W. Shield, G. F. F. Sinclair, R. S. Small, A. G. Smith, R. B. Smith, A. St G. Stephenson, P. D. Stewart, J. D. Sutherland, Rhoda M. Taylor, R. Troup, W. S. Tulloch, †Nina A. B. Verity, Doreen M. Waddington, G. C. Watt, C. C. Wedderburn, D. W. Whyte, A. W. Wilkinson, G. S. M. Wilson, G. Winchester, Leila E. Wynter, A. Young, R. G. B. Young.

DIPLOMA IN PUBLIC HEALTH.—P. G. Barrow, P. L. F. de Livera (*in absentia*), H. L. de Waal, A. M. Fraser, H. W. Hall, N. Husain (*in absentia*), P. L. Lai-Fook, E. A. Lawrence, V. P. M'Donagh, I. F. MacKenzie, V. D. Seevaretnam, S. Sivalingam, G. F. Valentine (*in absentia*), Agnes M. M. Hunter.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—K. B. Gore (*in absentia*), W. Happer, E. L. Lloyd, W. Mackie, N. S. Mohammed, W. Serle.

DIPLOMA IN PSYCHIATRY.—J. Carson, N. F. MacKenzie, J. H. Patterson.

DIPLOMA IN RADIOLOGY.—J. G. M'Whirter, J. R. Pierre (*in absentia*), T. Sprunt.

** Awarded Gold Medal for thesis. * Commended for thesis.
† Passed with honours.

The following prizes were presented: *Cameron Prize in Practical Therapeutics*: James Bertram Collip, M.D., F.R.S., Professor of Biochemistry in M'Gill University, Montreal, in recognition of his many contributions to endocrine therapy, and in particular his work on the parathyroid gland. *Ettles Scholarship and Leslie Gold Medal*: F. H. Robarts. *Scottish Association for Medical Education of Women Prize and Dorothy Gilfillan Memorial Prize*: Nina A. B. Verity. *Monat Scholarship in the Practice of Physic, Annandale Gold Medal in Clinical Surgery, Wightman Prize in Clinical Medicine, and Murchison Scholarship in Clinical Medicine*: J. Innes. *Buchanan Scholarship in Midwifery and Gynaecology, and Beaney Prize in Anatomy and Surgery*: R. A. Jamieson. *James Scott Scholarship in Midwifery and Gynaecology*: J. R. Frank. *Conan Doyle Prize*: A. Stadion. *Royal Victoria Hospital Tuberculosis Trust Gold Medal*: Elizabeth M'Callum. *Murdoch Brown Silver Medal in Clinical Medicine*: J. P. Baird. *Pattison Prize in Clinical Surgery*: A. W. Wilkinson. *Goodsir Memorial Fellowship*: A. Brown. *Freeland Barbour Fellowship*: A. I. Pirie. *M'Cosh Bursary*: I. A. Farfor. *Gunning Victoria Jubilee Prize in Bacteriology*: S Thomson *Gunning Victoria Jubilee Prize in Pathology*: W. M. Arnott. *Gunning Victoria Jubilee Prize in Therapeutics*: H. Scarborough. *Gunning Victoria Jubilee Prize in Zoology*: C. A. Green and S. Thomson (jointly). *Lewis Cameron Postgraduate Prize*: C. A. Green. *Lewis Cameron Undergraduate Prize in Bacteriology*: K. A Bisset and M. Gardiner (equal). *Wellcome Gold Medal and Prize in the History of Medicine*: J. Waterston. *Cunningham Memorial Medal and Prize in Anatomy*: G. M. Wilson. *Whiteside Bruce Bursary*: J. R. Lauckner.

An address was delivered to the new graduates by the Promotor, Professor Sydney Smith, M.D., F.R.C.P.Ed.

NATIONAL UNIVERSITY OF IRELAND

At a meeting of the Senate on July 15, with the Chancellor, Mr. Eamon de Valéra, LL.D., President of the Executive Council of Saorstát Eireann, in the chair, Dr. Denis J. Coffey, Vice-Chancellor, presented a report on the summer session, 1937, of the General Medical Council, on which he is representative of the University.

UNIVERSITY COLLEGE, DUBLIN

At a meeting of Convocation on July 17 the following medical degrees and diplomas were conferred:

M.B., B.Ch., B.A.O.—D. P. Murnaghan, G. M. FitzGerald, Kathleen A. Roche, R. Belton, J. Clyne, Maria Dempsey, J. P. Dodd, A. Eustace, J. D. Ffrench, P. J. Gilroy, G. J. Glynn, T. J. Gorman, N. N. Holmes, B. F. J. Kean, P. J. McEnroy, E. McKiernan, W. McManus, Nora McNally, J. O'Connell, R. M. P. O'Dolan, D. G. O'Sullivan, G. A. Peltier, B. MacM. Ramsay, Bridget F. Staunton.

D.P.H.—J. McHugh, P. H. J. Clarke, W. O. Cremin, J. M. Murphy, G. Davis, C. B. Mallen, P. O'R. Gavin, W. J. O'Brien, Mary B. Brady, J. J. Campbell, P. J. Fox, J. T. Guinan, J. P. Maher, P. J. O'Doherty, E. O'Shaughnessy.

B.Sc. (PUBLIC HEALTH).—J. A. Craig, W. O. Cremin, P. O'R. Gavin, J. McHugh, C. B. Mallen, J. M. Murphy.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh, held on July 22, with Mr. Henry Wade, President, in the chair, the following, having passed the requisite examinations, were admitted Fellows:

W. E. Austin, W. H. Bailey, D. Ballantine, E. E. Barnett, C. R. Chari, M. M. Cruickshank, R. H. Dale, W. K. House, J. Harkness, Agnes J. Herring, M. Jackson, K. G. W. James, H. I. Maister, A. R. A. Marshall, M. L. R. Morley, M. C. Moore, W. F. McGladdery, Margaret Fitz-H. Procter, J. C. Samis, G. I. Scott, I. H. Smith, S. L. Strange.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the Royal College of Physicians of Edinburgh was held on July 20, with the President, Dr. W. T. Ritchie, in the chair.

Dr. Francis Esmond Reynolds (Glasgow) and Dr. Charles Kelman Robertson (Edinburgh) were elected Fellows.

BRITISH POSTGRADUATE MEDICAL SCHOOL

The following constitute the Governing Body for the year 1937-8: Sir John Caulcutt (Chairman), Mr. Charles J. Allpass, Mr. W. Girling Ball, F.R.C.S., Sir Henry Brackenbury, LL.D., M.D., Viscount Dawson of Penn, M.D., P.R.C.P., Lieut.-Colonel H. R. Dutton, I.M.S. (ret.), Professor G. E. Gask, F.R.C.S., Dr. A. M. H. Gray, Mr. Somerville Hastings, F.R.C.S., Lord Horder, M.D., Mr. W. M. Goodenough, D.L., Miss L. Martindale, M.D., Sir Frederick Menzies, M.D., Sir Arthur S. MacNalty, M.D., Mr. H. J. Paterson, F.R.C.S., Sir Thomas Stanton, M.D., Sir Cuthbert Wallace, Bt., P.R.C.S., Sir William Willcox, M.D., Sir Alfred Webb-Johnson, F.R.C.S.; with Colonel A. H. Proctor, M.D., I.M.S. (ret.), as Dean and Secretary to the Governing Body.

COMBINED HOSPITALS UNIVERSITY ENTRANCE SCHOLARSHIPS

As a result of the examination held for the University Entrance Scholarships, offered by St. Bartholomew's Hospital Medical College, Guy's Hospital Medical School, and St. Thomas's Hospital Medical School, the following awards have been made:

H. V. Morgan (Gonville and Caius College, Cambridge), Scholarship at St. Bartholomew's Hospital; L. W. Smith (Sidney Sussex College, Cambridge), Exhibition at St. Bartholomew's Hospital.

G. E. H. Enderby (St. John's College, Cambridge), Scholarship at Guy's Hospital; G. T. G. Thomas (Gonville and Caius College, Cambridge), Exhibition at Guy's Hospital.

J. L. Pinniger (St. Edmund Hall, Oxford), Scholarship at St. Thomas's Hospital; M. G. Smith (Emmanuel College, Cambridge), Exhibition at St. Thomas's Hospital.

The Services

MEDICAL DIRECTOR-GENERAL, R.N.

Surgeon Vice-Admiral P. T. Nicholls, C.B., has been appointed Medical Director-General of the Royal Navy.

OPERATIONS IN PALESTINE

The names of Major H. Alcock, R.A.M.C., Group Captain K. Biggs, M.C., R.A.F.M.S., Wing Commander G. P. O'Connell, R.A.F.M.S., Squadron Leader G. E. Church, R.A.F.M.S., and Flight Lieutenant C. A. Rumball, R.A.F.M.S., have been brought to notice by the Air Officer formerly Commanding the British Forces in Palestine and Transjordan, in recognition of distinguished services rendered in connexion with the operations in Palestine during the period April to October, 1936.

Medical Notes in Parliament

The Summer Adjournment of Parliament is due to begin on July 30 and to end on October 21 unless the Speaker and the Lord Chancellor in the public interest call both Houses together at an earlier date. A new session is expected to be opened by the King on October 26.

The Collecting Charities (Regulation) Bill was read a first time in the House of Lords on July 22 on the motion of Lord Kennet, who, in introducing the Bill, explained it was to provide for the better regulation of collections for charitable, benevolent, or philanthropic purposes from house to house or in any place of entertainment or refreshment.

In the House of Lords, on July 26, the Finance Bill and the Milk (Amendment) Bill were read a second time. On the following day the Local Government Superannuation (Scotland) Bill was read a third time and passed.

Debates arranged in the House of Commons this week were concerned with the Mines Department, the co-ordination of defence, the cost of living, and Dominion affairs.

The Milk (Amendment) Bill passed through the report stage in the House of Commons on July 21 and was read a third time on July 23. On the latter day it was read a first time in the House of Lords.

The Royal Samaritan Hospital for Women Glasgow Order Confirmation Bill was considered by the Commons on July 21 and was read a third time on July 22, without amendment.

The Liverpool United Hospital Bill, as amended in committee, was considered on report in the House of Commons on July 22 and further amendments were made. The Bill was read a third time on July 26.

The Lords amendments to the Matrimonial Causes Bill were approved in the Commons on July 23. No allusion was made to lunacy as a ground for divorce. Also, on July 23, the Lords' amendments to the Cinematograph Films (Animals) Bill were accepted, and on July 26 the Lords' amendments to the Coal Mines (Employment of Boys) Bill were agreed to.

Pensions of Local Government Officers

In the House of Lords on July 19 the Local Government Superannuation Bill was considered in committee.

On Clause 5 (Power to admit employees of statutory undertakers and certain associations) Lord ADDISON moved to add a provision that where a local authority under Section 101 of the Local Government Act, 1929, made a grant to a voluntary organization for the provision of maternity and child welfare services, the provisions of Subsection (1) of Clause 5 should apply in relation to that organization and to health visitors and superintendents of welfare centres employed by those organizations as they applied in relation to statutory undertakers and to employees of those undertakers. Local authorities were empowered, when they came to an arrangement with voluntary organizations employing midwives, to arrange that the midwives so employed should be incorporated in the superannuation scheme as and when the local authorities took over the voluntary organizations. The discharge of duties under the Midwives Act was a statutory obligation on the local authorities, and the voluntary organizations in this case were performing these duties on behalf of the local authorities. The case was identical with that of officers employed in maternity and child welfare services. The officers in maternity and child welfare services employed by infant welfare associations were overlooked in the House of Commons, and it was to remedy that omission that he moved the amendment.

VISCOUNT GAGE asked Lord Addison not to press the amendment at this stage of the Bill. The clause as it stood was accepted by the Government as an amendment in the House of Commons. It related only to midwives employed by a voluntary organization with whom the authority responsible for midwifery services had made arrangements under the Midwives Act of last year. The duties imposed on the local authority, and consequently the services required of these midwives, were definite and specific; they were to be, so to speak, "on call," as and when required, to attend women needing the midwifery service for which the local authority was responsible. Their salaries were such as might be determined by the agreement and, in effect, the local authority indirectly paid those agreed salaries through the voluntary organization—an important point in the superannuation scheme. They were as nearly as might be in the same position as midwives directly employed by a local authority. The position of health visitors doing maternity and child welfare work was analogous, but not identical. The financial arrangements between the authority and the voluntary body were not the same. Services were not similarly specified, salaries were not specifically controlled, and subsidies were not so directly related to salaries. It was considerations of this kind which led the majority of the Selby-Bigge Committee to reject suggestions designed to secure the same object as this amendment. If an attempt were made to cover the case which Lord Addison cited, amendment of the Bill would logically have to be carried much further than he proposed. They could hardly differentiate between health visitors engaged on child welfare work and those similarly engaged on work in connexion with the blind, the tuberculous, and the mentally deficient as employees of voluntary bodies whose financial relations with local authorities were for the most part indistinguishable in principle from those of child welfare organizations. He did not wish Lord Addison and those for whom he spoke to regard this as necessarily the last word on the subject for all time. The Minister of Health had undertaken to explore the possibilities in another matter affecting the superannuation of nurses and health visitors. Consultation with the local authorities and others concerned might throw a different light on the considerations which, as at present envisaged, compelled him to ask that the amendment should not be pressed.

Lord ADDISON withdrew the amendment.

The Bill passed through committee.

The Bill passed through the report stage on July 22.

Marriage Bill

In the House of Lords, on July 19, Lord ELTISLEY moved the third reading of the Matrimonial Causes Bill. Lord DARYNGTON, in opposing the motion, said that it would be a very big step to make insanity a ground for divorce. Many of them had known of cases where men had returned to sanity after ten or even fifteen years.

The Bill was read the third time by 79 votes to 28, and passed. Among the Peers who voted for the third reading was Lord Dawson.

Animal Diseases and the Veterinary Service

During the debate on the second reading of the Agriculture Bill in the House of Lords on July 20 Lord ADDISON expressed the hope that some of the money voted to the eradication of disease would be devoted to research. With very inadequate finance an Agricultural Research Committee had been established on the lines of the Medical Research Committee. If, for a long time past, research into animal diseases had been organized and well directed, with pay such as would attract the right young men into it and would keep them in it, we should have been much further forward than now. He hoped that the expenditure under the Bill would not take the form of paying too much for animals found to be diseased, but would aim at seeking to remove the causes of disease, which could only be done by large-scale, patient encouragement of research.

Viscount BLEDISLOE hoped the time had come when the status of veterinary surgeons in this country would be improved. There were countries in which in some cases the medical and veterinary professions merged one into the other, as in Denmark, and in many countries there was not that disparity of status which unfortunately existed in this country and which kept some of the ablest and most scientifically minded men out of that branch of the medical profession.

The EARL OF GLASGOW said that in the more progressive counties in Scotland, where the local authorities had developed a co-ordinated medical, veterinary, and bacteriological service, they were concerned that the proposals of the Bill might seriously affect not only the veterinary services but the health services generally. In those health services the veterinary officer was only one link in the chain of control, the other links being the sanitary inspector and the county medical officer of health. Now it was proposed to break this chain, but, important as animal disease might be, public health was of more importance.

The House of Lords went into committee on July 22 on the Agriculture Bill. On Clause 18 Lord CRANWORTH moved to insert:

"The Chief Veterinary Officer of the Ministry of Agriculture shall supervise and direct such veterinary officers in the discharge of their duties and shall be responsible directly to the Minister in relation thereto."

The EARL OF FEVERSHAM said the matter had already been discussed in the House of Commons. Reference had been made to the practice followed in the Ministry of Health, but there was no statutory provision that compelled the Minister of Health to appoint a chief medical officer or said that the chief medical officer was to have direct access to the Minister. This was done in accordance with administrative convenience and at the wish of the Minister himself. It was the permanent secretary who was responsible for the efficient administration of the Department and who in turn was responsible to the Minister. It would be contrary to precedent for the chief veterinary officer of the Ministry of Agriculture to be responsible for other than his own veterinary work and that of the staff under him. There was no doubt that whenever representation to the Minister was necessary the chief veterinary officer would have access to him at any time to raise a point for which he was responsible.

The amendment was withdrawn.

On Clause 32 (Application to Scotland) Lord ROWALLAN moved to add a new paragraph to provide that the functions of the local authorities under the Diseases of Animals Act, 1894-1935, should be transferred to the Minister. He said that under the Bill three duties of local authorities under the Diseases of Animals Act would be transferred to the central veterinary service. These were routine veterinary inspection of dairy herds under the Milk and Dairies Legislation, tuberculin testing at veterinary inspection under the Milk (Special Designations) Order of the Department of Health for Scotland, and diagnostic inquiries into the various scheduled diseases, including tuberculosis.

Lord FEVERSHAM said it would cut right across the intentions of the central veterinary service if it were contemplated that the numerous activities of local authorities under the Diseases of Animals Act were to be effected by the central service. Grave difficulties would arise in administration of what was to be a service directed essentially to the better eradication of animal diseases.

The amendment was withdrawn.

The EARL OF GLASGOW moved to insert in Clause 32 (Application to Scotland) the following new paragraph:

It shall be the duty of officers appointed by the Minister to furnish any information reasonably required by the local authority or its medical officer of health in regard to any disease of animals affecting or likely to affect the health of persons resident in the area of the authority, and to trace the course of infection wherever reasonably practicable.

Lord STRATHCONA said it was recognized that the services of a veterinary inspector were and would still be required at times by local authorities to enable them to discharge their

functions in relation to public health. Provision was made in Clause 18 requiring the Minister to make arrangements for placing the services of veterinary inspectors at the disposal of local authorities. The services of veterinary inspectors would be made available for inspections of cattle carried out in consequence of notifications received from medical officers of health under the Milk and Dairies Acts or the Infectious Disease (Prevention) Act, 1890, that consumption of milk from a certain specified herd was likely to cause tuberculosis or was suspected to have caused some other infectious disease.

The EARL OF FEVERSHAM said that where a medical officer had been informed of a case of tuberculosis of bovine origin the inspectors, whether full-time or part-time, under the veterinary service would act in the closest co-operation with the medical officer in tracking the herd from which the disease arose. He hoped that practice would be followed a great deal more than it had been in the past. It not only benefited the large centres of population but the agricultural industry. It would be a means whereby the veterinary service could trace the disease which it wished to eradicate. He could give the most explicit assurance that this would be carried out.

The amendment was withdrawn.

Consideration of the Bill in committee was then concluded.

Factories Bill

The report stage of the Factories Bill was taken in the House of Lords on July 22. On Clause 2 (Overcrowding) the House agreed to an amendment moved by the EARL OF MUNSTER authorizing the chief inspector by certificates to exempt any workroom in which explosive materials are manufactured or handled from provisions laid down in the clause.

On Clause 42 (Washing facilities) an amendment was accepted on the motion of the EARL OF MUNSTER to provide that the facilities for washing "shall include soap and clean towels or other suitable means of cleaning or drying." The Earl of Munster also moved to insert a subsection providing that the Home Secretary might by regulation exempt factories from any of the requirements of the clause in cases of difficulty in obtaining an adequate supply of water or where accommodation was restricted but adequate and suitable washing facilities were otherwise conveniently available. The proviso was accepted.

On Clause 43 (Accommodation for clothing) an amendment was accepted allowing the Home Secretary to exempt factories from any of the requirements of the clause in special circumstances specified in the Regulations.

Lord FARINGDON moved to provide on Clause 53 (Underground rooms) that no underground workroom should be excepted from the clause unless certified by the inspector for the district to be suitable for the purpose on hygienic grounds, and in particular as regards construction, light, ventilation, and adequate means of escape in case of fire. The EARL OF MUNSTER said the clause as it stood would be more effective in securing improvement in underground rooms. The issue of positive certificates by inspectors tended to tie the hands of the staff in future in raising standards. The amendment was negatived.

After Clause 54 (Basement bakehouses) Lord FARINGDON moved to insert a new clause prohibiting baking between 11 p.m. and 5 a.m. except as allowed by special order of the Home Secretary. The EARL OF MUNSTER said the report of the Committee on Night Baking had been very recently received and demanded a more thorough examination than had so far been possible. It would not be possible for the Government to entertain any question of legislation on the subject during the present session. The Minister of Labour was willing to enter into negotiations with representatives of the two sides without delay to establish some joint machinery whereby the trade might devise means for ameliorating conditions.

The amendment was negatived.

On Clause 73 (Reduction of weekly hours of work of young persons under 16) Viscount SAMUEL moved to provide that after three years from the commencement of the Act the maximum weekly hours for young persons under 16 should be reduced to 40, while 44 should be the maximum in lieu of 48 in the exempted trade. The EARL OF MUNSTER said it would be impossible to go further at the present time than the proposals in the Bill, but the Government expected at no distant date to make a further advance. The proper way to deal with the matter was to consider it in the light of the experience which would be gained during the next few years when industry had adjusted itself to the reduced hours laid down in the Bill.

Lord Samuel's amendment was defeated by 50 to 14.

On Clause 101 (Certificate of fitness for employment of young persons) an amendment was accepted on the motion of the EARL OF MUNSTER to insert the following new subsections:

"Where the examining surgeon so directs in the certificate, any such condition as aforesaid shall, so far as relates to the employment in respect of which the certificate was issued or other employment in a factory in the occupation of the same occupier, continue to have effect when the young person has attained the age of 16; but unless such a direction is made the condition shall cease to have effect when the young person attains the age of 16, and shall in any case cease to have effect when the young person attains the age of 18.

"Where a certificate under this section is subject to a condition requiring re-examination after an interval specified in the certificate, the examining surgeon on such re-examination may vary the certificate or may revoke the certificate as from such date as he may direct; and if the certificate of a young person is revoked before he attains the age of 16 he shall not remain in any employment to which the certificate relates, and subsection (1) of this section shall thereafter have effect as if no certificate had been issued in respect of that young person."

The amendment was agreed to.

A new clause was added dealing with the application of the Act to electrical stations, including the application of the provisions of Part IV with respect to special regulations for safety and health.

The report stage was completed.

The House of Lords read the Factories Bill a third time on July 23.

"Deplorable" Housing Conditions in Carmarthen

Mr. JAMES GRIFFITHS inquired on July 22 whether the attention of the Minister of Health had been called to the report made by the medical officer of health for the county of Carmarthen, drawing attention to the urgent need for a maternity home in the county, and to the deplorable housing conditions in some parts, in particular to a case in which a midwife had reported that she had been compelled to use a step-ladder to reach a patient in one house; and whether, having regard to the high incidence of maternal mortality and of tuberculosis in the county, he would cause an inquiry to be made into the housing conditions there. Sir KINGSLEY WOOD replied that his attention had not been drawn to the report. Provision of a maternity home was being actively considered by the Carmarthen County Council in conjunction with the Llanelly Town Council. He was aware of the housing conditions in the county, and was arranging for his officers to confer in the matter with the local authorities concerned.

Rehabilitation After Accidents

Sir ARNOLD WILSON, on July 26, asked the Minister of Health what, if any, steps he had in contemplation to give effect to the recommendation of the interdepartmental committee on the rehabilitation of persons injured by accidents, with particular reference to the treatment of the 200,000 cases of fractures which occurred annually. Mr. BERNAYS replied that the Minister had already sent copies of the interim report of this committee to the county and county borough councils in England and Wales, with a covering circular. In this report the committee expressed the hope that they would be in a position to present a further report without delay, and the Minister did not propose to take any further general action on this subject until he had received that report.

Report of Committee on Night Baking.—Replying, on July 22, to an inquiry by Mr. Banfield about the report of the Committee on Night Baking, Sir SAMUEL HOARE said the committee, by a majority, advised against statutory prohibition of night baking. Its view was that such prohibition would fall far short of providing comprehensive and effective relief to the night baker from the serious social disadvantages under which he laboured. The situation presented in the report demanded a more thorough examination than had been possible, and he could not at present make any final announcement of the Government's views on the main issue. In view of the nature of the report it would not in any case be possible for the Government to entertain any question of legislation on the subject during the present session. The committee had suggested that some recognized body should be set up on which representatives of both sides of the trade might meet together to thrash out difficulties and devise means for amelioration of conditions. The Government was prepared to take action to give effect to this.

Industrial Accidents Increase.—Answering Mr. Alfred Short on July 22, Sir SAMUEL HOARE said he much regretted the increase in industrial accidents during 1936 as compared with 1935. As the Chief Inspector pointed out in the introduction to his report, the increase in the number of accidents was partly due to increased employment. Statistics over a period of years showed that the rate of accidents in proportion to the number of persons in employment was decreasing. If any large reduction of accidents was to be obtained it must be through the exercise of increased care by both employers and workpeople. This could best be secured through the development of safety organizations. The Factory Department had made every effort in the past to promote such development, and would continue to do so.

Compulsory Pasteurization.—Mr. WM. LEACH asked the Minister of Health on July 22 to have a searching inquiry made into the allegations against raw milk, "in view of the many loopholes in the evidence adduced in support of the allegations against raw milk in connexion with outbreaks of scarlet fever and typhoid fever," before he sanctioned any general claim for the compulsory pasteurization of milk. Sir KINGSLEY WOOD replied that he was satisfied that in all recent cases of this kind which had been investigated by his department, and in which the outbreak was traced to the consumption of raw milk, the evidence on this point was conclusive. He recalled that the Cattle Diseases Committee of the Economic Advisory Council, which reported in 1934, reviewed the question of the danger of the spread of these diseases through the medium of milk before it recommended compulsory pasteurization in large towns. He did not consider it necessary to institute any further inquiry into this question.

The Paratyphoid Outbreak in Liverpool.—Asked on July 22 what was the cause of the Liverpool outbreak of paratyphoid fever in January last, Sir KINGSLEY WOOD said the medical officer of health of the city was of opinion that the outbreak was probably caused by the infection of food by a carrier of the disease.

Tuberculosis Statistics.—Sir KINGSLEY WOOD furnished on July 22 the following statistics on the incidence and mortality:

Tuberculosis (All Forms)

	Cases	Deaths
Norway (1934)	5,521	3,225
Japan (1934)	*	131,525
Germany (1934)	*	47,179
Switzerland (1935)	*	4,035
England and Wales (1935)..	59,623	29,201

*Information not available.

Notes in Brief

During 1936 six persons under 16 years of age were killed and 1,188 injured (disabled for more than three days) at mines under the Coal Mines Act in Yorkshire.

Mr. Chamberlain told Mr. B. V. Kirby, on July 14, that he could hold out no hopes of special facilities being given for the passage of the Local Authorities (Hours of Employment in Connexion with Hospitals and Institutions) Bill.

Medical News

The House of the British Medical Association, including the Library, will be closed from 6 p.m. on Friday, July 30, to 9 a.m. on Tuesday, August 3 (Library 10 a.m.).

The Royal College of Physicians of London will be closed from Monday, August 2, to Saturday, September 11, both days inclusive.

In our advertisement columns this week there appears a vacancy for the University Chair of Pharmacology, tenable at the College of the Pharmaceutical Society of Great Britain, at a salary of £1,200 per annum.

The sixteenth Carlsbad international postgraduate course, with special reference to balneology and balneotherapy, will be held at Carlsbad from September 12 to 18. Further information can be obtained from Dr. Edgar Ganz, Carlsbad.

The twenty-first International Congress against Alcoholism will be held at Warsaw from September 12 to 17 at the University Józef Pilsudski. Among the subjects to be discussed are alcohol and work: the campaign in Poland against alcoholism: the action of alcohol on the brain, and beer as the cause of psychoses; racial, environmental, and age factors; the work carried on in Germany, the Ukraine, and the United States; fiscal considerations and sociological difficulties; and the possibilities of international collaboration. The preliminary programme can now be obtained from the general secretariat of the congress, 24, Chocimska Street, Warsaw.

The Minister of Health has sanctioned the borrowing of £488,666 by the Lancashire Mental Hospitals Board for works in connexion with the extension of the Brookhall certified institution for mental defectives, to provide accommodation for 1,326 additional patients, bringing the total accommodation of the institution up to 2,098. The new accommodation will include a hospital, school, workrooms, recreation hall, staff cottages, and administrative buildings.

Lord Nuffield and Mr. Edward Meyerstein have been made vice-presidents of Papworth Village Tuberculosis Settlement. In 1937 Lord Nuffield has given £25,000 to the settlement, and Mr. Meyerstein £20,000.

Miss Hurdon, M.D., C.M., retires from the directorship of the Marie Curie Hospital, Fitzjohn's Avenue, N.W., at the end of this year. Dr. M. D. Gilmour has been appointed to succeed Miss Hurdon as director from January 1, 1938.

Dr. Leslie Winter Dryland and Lieut.-Colonel Josiah Walker, M.C., T.D., have been appointed Deputy Lieutenants for the County of Northampton.

Dr. William J. Kerr of San Francisco was elected president of the American College of Physicians at the annual meeting recently held at St. Louis.

Sir Herbert Samuelson, acting on medical advice, has resigned the office of Chairman and Treasurer of University College Hospital, which he has held since 1927. Sir Courtauld Thomson will hold these offices pending the appointment of a successor.

The issue of *Il Policlinico* (Sez. Prat.) for July 12 contains a sympathetic obituary notice of Sir Squire Sprigge, late Editor of the *Lancet*.

The June issue of *Norsk Magazin for Laegevidenskapen*, the organ of the Norwegian Medical Association in Oslo, is dedicated to Francis Harbitz, professor of morbid anatomy and forensic medicine, on the occasion of his seventieth birthday, and contains a bibliography of his writings from 1895 to 1937.

The Air Ministry has notified aircraft owners that it intends to make the carrying of oxygen compulsory during flights by commercial aircraft at altitudes of 15,000 feet.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Attiology Westcent, London.*
SECRETARY, *Mediseera Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh;* telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin;* telephone 62550 Dublin).

QUERIES AND ANSWERS

Successive Miscarriages

Dr. O. SYDENHAM writes: I should be very glad if any of your readers could suggest treatment for a patient who has had five successive miscarriages at ages varying from nine weeks to four months. There is no physical abnormality, and her Wassermann reaction and the husband's are negative.

Weight of Twins

Dr. H. J. CLUTTERBUCK (Llanelly) writes: I have to-day delivered a multipara of twin girls, both being breech presentations. The first child weighed 9½ lb. and the second one 8½ lb. In my fairly long experience of midwifery I have never seen such splendid specimens, and I should like to know what is the record weight for twins born alive.

Agranulocytosis and Rheumatism

Dr. C. J. YOUNG (Bradford) writes: With reference to the question asked by Mr. L. A. Riddell (*Journal*, July 24, p. 197), the possibility implied was considered, but rheumatic fever has not so far been incriminated as a cause of agranulocytosis.

LETTERS, NOTES, ETC.

Medical Books for a Mission Hospital

Dr. HOPE TRANT (Mwenzo Hospital, P.O. Isoka, Northern Rhodesia) writes: I ask leave to use your columns to beg for discarded medical books for this mission hospital. There are probably among your readers practitioners who take a pride in keeping their medical libraries up to date, or who, for various reasons, must keep abreast of the latest developments. May I ask these, when they are replacing their older editions with newer ones, to be so kind as to put aside the older ones for us. The Livingstonia Mission, to which this hospital belongs, has a chain of native hospitals in Northern Rhodesia and Nyasaland. They are run on pitifully small grants ranging from £40 to £200 per annum, and, as the medical missionaries' salaries are also very small, there is little or no money for the purchase of new medical books. On isolated stations medical works are our consultants and guides, and if these are antiquated and out of date, so will our practice become. If, therefore, any of your readers would be kind enough to send us, by book post to the above address, medical books of any kind, but preferably not older than 1926, they would earn our heartfelt thanks. Should duplicates be received, they will be passed on to another station.

Education for Nursing

At the opening meeting of the International Council of Nurses Quadrennial Congress Mr. Kenneth Lindsay, M.P., Parliamentary Secretary to the Board of Education, said that the Board was doubly interested in the nursing profession. In the first place, the local education authorities throughout England and Wales employed a nursing staff equivalent to 2,574 whole-time nurses, who assisted the medical officers at school inspections and worked in the school clinics, and also followed up the work in the schools by visits to the children's homes and by interviews with their parents. The Board was naturally concerned with the education of so large a number of women in the employment of the authorities, and too much thought could not be given to providing the training which would best fit them for the special duties required in the school medical service. In the second place, the Department was interested in the education of nurses because it was anxious that the schools should help the nursing profession as far as possible by supplying the kind of girls that were needed.

Bonomo and the Itch-mite

Dr. CONOR J. O'L. MAGUIRE (Co. Mayo) writes: Reading your annotation on "Bonomo and the Itch-mite" (*Journal*, July 17, p. 124) suggests that it may be of interest to know that the parasitic origin of scabies was well known in the west of Ireland, and that the knowledge must have dated very far back. I remember when a boy seeing women searching the hands of children who had scabies with a fine sewing needle and picking out the mite (or, as they called it, the fleshworm) on the point of the needle. These women were illiterate Irish-speaking people, to whom the knowledge must have been handed down through generations. There is an old Irish proverb relating to the itch-mite which is called *Frigh*: "Is lugha na frigh ughdhar an droch-adhbar"; which is translated: "Smaller than the itch-mite is the beginning of evil" (or malignant disease).

Thinking and Trying

In the "Nova et Vetera" article on page 120 of our issue for July 17 it was stated that Sir David Wilkie, in his address on "The Scottish Tradition in Surgery," connected John Hunter's advice, "Don't think; try it," with immunization of human beings by giving them cow-pox. Professor J. A. Nixon, however, with a desire to put the story in its right setting, informs us that Baron gives the whole letter in his *Life of Edward Jenner* (vol. 1, p. 33), showing that Hunter was referring to some observations on hedgehogs. The letter runs:

> "I thank you for your experiment on the hedgehog; but why do you ask me a question by the way of solving it? I think your solution is just, but why think,—why not try the experiment? Repeat all the experiments upon a hedgehog as soon as you receive this, and they will give you the solution."

Cheap Milk for Mothers and Children

A leading article in the *Journal* of July 17 discussed the memorandum on cheap milk for mothers and children issued by the Children's Minimum Council. The Secretary now informs us that there has been such a demand for this memorandum that the Council has decided to publish it in pamphlet form, and it will be on sale at the office, 72, Horseferry Road, S.W.1 (price 6d. a copy).

Bermondsey Public Solarium

The laying of the foundation stone of the Bermondsey Public Health Centre was reported in the *British Medical Journal* of September 28, 1935, and the Centre was officially opened by the mayor on November 7, 1936. We have now received a thirty-two-page booklet describing the new light treatment department, or solarium, which occupies almost the entire first floor of the Public Health Centre. A light treatment department was first introduced in Bermondsey in 1926, when the capacity of the department was 350 per day. Now it is 1,600, and up to fifty patients can receive treatment simultaneously with the present apparatus. The booklet is issued by Hanovia Ltd. of Slough, who designed and installed the equipment for the new department.

Dr. H. V. CRABTREE (Torquay) wishes to announce that he is no longer associated in partnership with the Southern Medical Agency, and that in consequence of his withdrawal all correspondence for that agency should be addressed to 1, Albert Street, Birmingham.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

85 Diphtheritic Endocarditis

G. J. BUDDINGH and K. ANDERSON (*Arch. intern Med.*, April, 1937, p. 597), who record an illustrative case, state that only six examples of acute vegetative endocarditis caused by the diphtheria bacillus have hitherto been reported. In three of these cases the micro-organisms, while presenting the morphological and cultural features of the diphtheria bacillus, were not virulent to guinea-pigs. The authors' patient was a boy, aged 16, who suffered from rheumatic heart disease, and whose principal symptom was repeated epistaxis which required packing. Death took place after seven months' illness with symptoms of ulcerative endocarditis. At necropsy a large friable fibrinous vegetation from which virulent diphtheria bacilli were grown was found along the edges of the mitral valve; the portal of entry was most probably the nasopharynx, in which ulceration had been caused by the packing.

86 Cramp in the Leg

J. WILDER (*Wien. klin. Wschr.*, June 11, 1937, p. 895) has studied for many years the occurrence of cramp in the calves, and has found this phenomenon to be more common than is usually supposed. A maximal tonic contraction of a muscle takes place, which lasts for from one to six minutes, giving rise to intense pain which leaves the muscle tender for several days but which does not impede locomotion. Powerful passive stretching of the muscle may cut the attack short. Various aetiological factors are cited in the literature; these include metabolic disturbances, such as gout, diabetes, kidney disease, and pregnancy; poisons—for example, alcohol, lead, and arsenic; vascular diseases; static and dynamic factors, as, for instance, flat-feet and occupational dysfunction; neuritic diseases; and avitaminoses. Wilder examined 2,443 cases, and found a history of cramp in 33 per cent. of healthy persons and 40 per cent. of diseased persons. The symptoms usually occurred in the fourth decade, and slightly more often in men than in women; manual and sedentary workers were equally affected. High uric acid values were more common in cases with cramp than in normal cases. Normal diuresis was found in 31 per cent. of these cases, increased diuresis in 24 per cent., and decreased diuresis in 46 per cent., indicating a renal factor in the aetiology of the condition. Cramps were more often noted in alcoholics than in teetotallers. In a series of 1,413 patients suffering from various diseases Wilder found that this condition was common in those with arteriosclerosis, neurosis, chronic arthritis—especially spondylarthritis—and flat-feet. In certain conditions—as, for example, hyperthyroidism—cramps were less often found than in healthy persons. In many cases diathermy and a vegetarian diet, given to lower the hyperuricaemia, controlled the cramp. The author believes that it is due to a lowering of muscular tone, and that irritation of the peripheral nerves and the accumulation of uric acid in the blood are exciting factors.

87 Hypertension in Young Adults

M. A. TOURNIARE (*J. Méd. Lyon*, June 5, 1937, p. 331) draws attention to a not uncommon condition occurring chiefly in young persons, aged between 20 and 26, which he terms "hypertension sympathique solitaire." Fifteen cases have been studied in the past six years, and the disease was latent in five; the remainder complained of dyspnoea and palpitations, and a few of precordial pain following exercise, emotional disturbance, or a meal. The systolic blood pressure was found to be moderately increased; the diastolic pressure was in all cases normal. In some cases the blood pressure was raised following exercise, but fell after a period of rest. In no case could cardio-vascular disease be discovered, and in three cases the basal metabolic rate was raised. Tourniare points out that this condition must be differentiated from true juvenile hypertension, in which the diastolic readings are high and do not fall, even after long periods of rest. The patients complain of the classical symptoms of arterial hypertension, and there is usually hypertrophy of the left ventricle. In the former the condition is stationary, and never ends in cardiac failure. In the latter the condition is progressive and the prognosis grave. The author believes that the former type of hypertension is due to a simple hyperactivity of the sympathetic nervous system and belongs to the group which includes nervous tachycardia, and is characterized by hypertension, tachycardia, a raised metabolic rate, and the absence of hormonal dysfunction; these symptoms occur either alone or in conjunction with one another. He is of the opinon that "hypertension sympathique solitaire" is a result of a functional disturbance of the vasomotor centre and the hypothetical centre which governs the basal metabolism. Tourniare states that the sole treatment required is that of progressive readaptation of the heart to effort, aided in severe cases by radiotherapy as used in nervous tachycardia. Rest, cardiac tonics, drugs for lowering the arterial tension, and sedatives for the sympathetic nervous system are all measures which the author condemns.

Surgery

88 Fibrocystic Disease and Hyperparathyroidism

J. BAUER and A. JUNG (*Rev. Chir.*, Paris, April, 1937, p. 284) report an interesting case of a woman of 34 years who complained of a violent pain in the right thigh and hip after a fall. A diagnosis of a neoplastic metastasis in the right femur was made radiologically, and radiotherapy was given with some success. Two years later there were similar pains in the left thigh, and both hips were treated by radiotherapy with no result. There was a history of an early fracture of the right radius which had left a deformity, although function was good. Menstruation had not begun until the age of 20, and had now ceased. The patient was married, but she had no children. Radiological examination showed a generalized osteoporosis and the presence of numerous areas of bone-absorption. These appearances suggested that the patient was suffering from generalized fibrocystic osteitis. Radiography showed the characteristics of fibrocystic disease, and laboratory tests confirmed this diagnosis. Although no parathyroid tumour could be seen or felt it was assumed that there was one, and operation revealed a large adenoma in the region of the right inferior thyroid artery, which was removed. Pain disappeared after operation, but a spontaneous fracture occurred in the left femur and was put up in extension. The day after the operation the sign of Chvostek was seen, first on the left side of the face, then on the right, and there was paraesthesia in the arms and leg. Gluconate of calcium was given intravenously and by the mouth. A typical attack of tetany developed, and there was a sudden alteration in the blood calcium content, which fell to 70 milligrammes the day after operation. Ammonium chloride was then given, and later a coffee of gluconate of calcium. The condition of the patient gradually improved and the fracture united satisfactorily. The authors consider that this case illustrates the influence of the parathyroid hormone on the osteoclastic resorption of bone.

89 Carcinoma of Vater's Ampulla

G. NEMÉNYI (*Zbl. Chir.*, June 5, 1937, p. 1337) describes a new operative technique for carcinoma of Vater's ampulla. He covers the stump of the pancreas with the descending part of the duodenum, the anterior wall of which remains attached to the horizontal inferior part of the duodenum in the form of a flap. In this way the pancreas is covered with a relatively mobile piece of intestine lined with peritoneum. Instead of the blind occlusion of the superior horizontal part of the duodenum combined with a posterior gastro-enterostomy, the author recommends an anastomosis between the horizontal superior part of the duodenum and the jejunum. The jejunal loop used for the anastomosis is also provided with a Braun's anastomosis in order to prevent a back-flow into the duodenal segment overlying the head of the pancreas, since this is likely to give rise to pancreatitis.

90 Enlarged Supraclavicular Glands

H. SCHNEIDER (*Med. Klinik*, May 21, 1937, p. 699) states that the presence of carcinomatous metastases in the left supraclavicular fossa from a primary tumour in the stomach, intestine, or uterus has been recognized since the time of Virchow. The glands are enlarged, painless, and firm; they lie superficially, and are easily moved under the skin. In Schneider's opinion they are uncommon, but they may be present when a primary carcinoma cannot be found clinically. In the presence of the glands the primary tumour is usually regarded as inoperable, but the author believes that such a decision is untenable. He cites cases in the literature and reports a case of his own in which primary carcinoma existed together with enlarged supraclavicular glands, which were not metastatic but tubercular. He suggests that in all cases a gland should be excised and examined histologically, so that an operable tumour may not be overlooked and the patient labelled as incurable. He points out that carcinoma and tuberculosis quite often coexist. In some cases carcinoma occurs in old healed tuberculous foci; in others metastatic and tubercular glands occur together; a new tuberculous lesion may be implanted on a carcinoma; and chronic tuberculosis and carcinoma do occur together.

91 Embolism after Injecting Varicose Veins

A. WESTERBORN (*Acta chir. scand.*, May 1, 1937, p. 321) calculates that, between 1927 and 1934, in all the ninety-three Swedish hospitals about 30,000 patients were given intravenous injections for the treatment of varicose veins. There were eleven deaths from pulmonary embolism, of which six were verified at necropsy. There were also six cases of pulmonary embolism with recovery. The mortality was therefore 0.036 per cent., or, if two of the doubtful fatalities be excluded, 0.03 per cent. For the purpose of comparison the author has collected from eighty-two Swedish hospitals the records of 6,994 operations for varicose veins from 1921 to 1925; this length of time was chosen because it approached most closely to the subsequent injection period. There were eighteen deaths from pulmonary embolism, making the post-operative mortality from embolism 0.26 per cent. The author has correlated the fatal and non-fatal cases in his own material and in the world literature with the various drugs injected, and he has not found any significant relationship between the type of solution employed and the incidence of embolism. This may be due, however, to the fact that the emboli in question were derived from secondary coagulation thrombi and not from the original injection thrombus; in none of the author's six cases coming to necropsy had the original injection thrombus become detached. He traces post-injection pulmonary embolism to an infection, either local or general, to defective circulation, and to an individual predisposition to thrombus formation. Old age is also an important factor; all the author's patients were over 45. The influence of a defective circulation is increased by immobilization, and so he advises that patients should be kept out of bed as much as possible after an injection.

92 Painful Calcanean Spur

H. SPITZY (*Münch med. Wschr.*, May 21, 1937, p. 807) reports the results of a simple surgical operation carried out in seventy cases of painful calcanean spur. He considers that the pain is mainly due to traction by muscles and fasciae, and only partly to the pressure caused by the weight of the body on the foot. He therefore cuts through the muscles and fasciae at their point of attachment to the spur by means of a tenotome. The technique, which is very simple, is described in detail. Approximately two-thirds of the patients treated in this way were cured; nine cases came back with other complaints, such as flat-foot, arthritis of the foot, etc.; and in two cases the operation failed.

Therapeutics

93 Gold Salts in Chronic Carditis

M. WYBAUW (*Scalpel*, Liége, June 12, 1937, p. 749) gives a detailed report of eleven cases of chronic progressive carditis in adults in which treatment by gold salts was given with good results. The majority of cases occurred in women, and there was often a family record of tuberculosis or rheumatism. The onset of the cardiac lesion was due to varying causes such as angina, pleurisy, pleuropneumonia, or rheumatism. In some instances no such cause could be traced, and the patients had previously been in good health. The symptoms were loss of weight, anorexia, profuse sweating, and muscular asthenia. Acute cardiac pain was common and was paroxysmal, while palpitations and dyspnoea were usually present. Diagnosis of the simple forms of infective endocarditis may be uncertain, but radiology and electrocardiography are indispensable in determining the degree of myocarditis and in demonstrating the condition of the heart muscle. The laboratory tests were also of diagnostic value, and showed the sedimentation rate to be increased, while leucocytosis, lymphocytosis, and eosinophilia were generally present. In the eleven cases reported myochrysine was given in eight instances, oleochrysine in three, allochrysine in one, and both oleochrysine and myochrysine in another case. The immediate results were successful, and the general condition of the patients improved. Cardiac function was better, pain was relieved, and the dyspnoea was diminished. Treatment appeared to have arrested the development of the disease, although it did not cure it. In many cases improvement continued, although the end-results of the treatment have yet to be estimated. Particulars of the dosage and the general treatment are given.

94 Acute Osteomyelitis

G. BAGGIO (*Rif. med.*, May 29, 1937, p. 779) reviews the literature and records eleven cases of osteomyelitis affecting the femur, tibia, scapula, rib, or ilium in which no operation was performed, and there was only one death. Cardiac stimulants were administered, an early assimilated diet was given, and the affected part was immobilized and continuously treated with hot fomentations. In all but the single fatal case the acute inflammation subsided spontaneously either by the evacuation of an enormous quantity of pus through the skin or by absorption. While admitting that his cases are few in number and that further investigation is desirable, Baggio maintains that osteomyelitis may be cured in the acute stage without any surgical operation.

Ophthalmology

95 Aetiology of Squint

A. BIELSCHOWSKY (*Amer. J. Ophthal.*, May, 1937, p. 478) points out that there is still no satisfactory explanation squint, instancing the frequent failure of Donder's accommodative theory. Three factors form a basis of investigation: (1) mechanical factors, (2) excessive innervation, and (3) a combination of both. Each may produce a periodic squint, but it is only in the presence of a weak fusion faculty that this condition becomes permanent. Of normal persons 80 per cent. have a latent squint, which may develop if the fusion faculty is suspended. Prolonged excessive innervation or mechanical factors may result in secondary changes in the muscles. Ocular torticollis is due to trochlear paresis, congenital or acquired, or to an anomalous insertion of the internal rectus. The author stresses the importance of heredity; the parents do not necessarily show a visible squint, but there are neuropathic tendencies. Failure to obtain binocular vision after operation or training may be due to horror fusionis or aniseikonia.

96 Uveitis

A. L. BROWN (*Amer. J. Ophthal.*, June, 1937, p. 583) has used typhoid H antigen intravenously, together with paracentesis, with good results in the treatment of all forms of uveitis except the syphilitic or tuberculous types. Acute affections of the uveal tract responded best. Probably the antibodies present in the eye interfere with the activator as it reaches the uvea, or they unite with available receptors and render the activators inert. The same treatment has been used as a prophylactic against sympathetic ophthalmia in cases of traumatic laceration of the ciliary body.

97 Pathogenesis of Acute Glaucoma

A. BRAV (*Med. Rec.*, June 2, 1937, p. 447) is dissatisfied with most of the theories advanced on this subject. He believes that acute glaucoma is caused by increasing pressure on Schlemm's canal from hypertrophy of the ciliary processes. The proper use of optical corrections, which had been prescribed first before the age when prodromal symptoms might be expected, would prevent the onset of this condition. Eserine, by pulling upon the ciliary body, and iridectomy, by producing a cyclodialysis, both release pressure on the canal of Schlemm.

98 Spasmodic Retraction of the Upper Lid

J. VOISIN (*Arch. Ophthal.*, Paris, May, 1937, p. 391) distinguishes between an enlarged palpebral fissure which is self-evident and that elicited on examination of the muscular movements. The term "retraction" should be reserved for the former class, of which a special section is here considered. The retraction is usually slight, exposing a little sclera above the cornea. It is seen in many cases allied to Graves's disease, in irritation of the cervical sympathetic, and some dental affections, and as a sequel to encephalitis, cerebral lesions, cerebral tumour, hydrocephalus, and syphilis. It may be brought about by a hypertony of the smooth or the striated muscle actuating the upper lid, and may be due to a process of decerebration or to an irritation.

99 Fundus Lesions in Polycythaemia

M. COHEN (*Arch. Ophthal.*, Chicago, May, 1937, p. 811) differentiates primary polycythaemia from the secondary type due to congenital heart disease, emphysema, stenosis of the pulmonary artery, and dehydration of the tissues, and from the hypertonic type which is associated with arteriosclerosis and cardiac and renal disease. The associated cyanosis of the retina is only visible in the main blood vessels, the condition of the rest of the fundus being obscured, except in albinos, by its pigmentation. Sometimes the cyanosis is most marked in the physiological cup. Any lesion of the fundus is due to venous stasis; there were no lesions in the cases of secondary polycythaemia in the author's series. He reports oedema of the disk, retinal haemorrhages, white lines along the veins, and venous thrombosis. The prognosis depends upon the severity of the disease in the primary, and of the exciting condition in the secondary, type. In the former venesection, phenylhydrazine, and irradiation are helpful: in the latter the causative disease must be attacked.

Obstetrics and Gynaecology

100 Lightening

RUDOLF (*Surg. Gynec. Obstet.*, May, 1937, p. 906) discusses the phenomenon of lightening during the last weeks of pregnancy. He suggests five mechanisms by which the presenting part might descend into the pelvis. The first is the formation of the lower uterine segment, which is progressively demonstrable in frozen sections from the second month to term, and clinically recognizable as Hegar's sign. The measurements compare fairly accurately with those taken at Caesarean section. At the thirty-sixth week the lower uterine segment relaxes so as to accommodate the descent of the presenting part in response to intra-abdominal pressure. Relaxation is shown by the flattening of the cervix and the shortening of the distance between cervix and fundus. Nevertheless, lightening is sometimes experienced even though the head remains high. The second mechanism is the relaxation of the soft parts, due possibly to "relaxin," though this has not yet been demonstrated in the human female. When the cervix shows no appreciable descent and the foetal head is high but can be pressed into the pelvis relaxation has failed to take place; this abnormality is functional, not mechanical. Mobility of the posterior attachments is the third mechanism. The yielding of the muscle fibres in the posterior ligaments allows for the noticeable increase of anteflexion and anteversion, the anterior attachments providing a pivot. After labour has begun the posterior wall has to be pulled up to the level of the anterior attachments. This is made possible by a further yielding of the utero-sacral ligaments and an equal dilatation of the lower segment, together with the straightening of the birth canal. The fourth mechanism is the relaxation of the abdominal muscles, which occurs gradually or suddenly, as, for example, after a meal. The author suggests that the stimulus comes from pressure of the descending part upon the uterus or intrapelvic soft tissues, by way of the segmental reflex arcs which innervate the abdominal muscles, and the sensory influences which keep them at a lower tone than usual. The last mechanism is the cephalo-pelvic relation, which is mechanical and, if faulty, can be diagnosed by inability to press the presenting part into the brim. This demonstration of the sequence of the vertical changes in the three portions of the uterus shows the purpose of the phenomenon of "lightening" to be preparatory to labour and its value as a clinical guide.

101 Intravaginal X-Ray Treatment

F. ERICHSEN (*Zbl. Gynak.*, June 5, 1937, p. 1330) is satisfied that he has had better results in the treatment of inoperable cervical carcinoma since he introduced six years ago a supplementary x-ray treatment by a Schaefer-Witte tube introduced into the vagina. Primary parametrial or secondary pelvic wall deposits are thus more accessible, and in contrast to radium treatment the use of a very high irradiation dosage is compatible with the protection of neighbouring healthy tissues. The general scheme of treatment is: (1) radium, 4,000 to 5,000 milli-

gramme-hours being given; (2) percutaneous *x*-radiation, 1,800 *r* being applied from four to six front, back, and side fields, and 800 *r* from a perineal field; this is alternated with (3) 1,600 to 2,000 *r* at a depth of 5 cm. directed to the right and left pelvic walls from the intravaginal water-cooled tube. Increase beyond the last-named dose is useless if not harmful, and the whole treatment occupies about forty days. Disturbances of rectal and vesical function may follow, but no fistulae developed; the lateral vaginal walls showed transitory appearances of membranous inflammation. In inoperable (Groups III and IV) patients thus treated, 38 per cent. were living and symptom-free from one and a half to four years later, as well as three out of twelve patients who were treated for local recurrences.

102 Endometrioma

ROCMANS and PETITFRERE (*Brux. méd.*, May 2, 1937, p. 1001) define an endometrioma as a tumour which possesses the characteristics of endometrium but which occupies an abnormal position. It occurs most often in young women and may be situated in various regions. Two cases are reported, in one of which the tumour was on the upper part of the broad ligament and in the other it was adherent to the recto-vaginal septum. In the first case the patient had suffered from pain in the right iliac fossa for four years. This pain, which radiated to the right hip and the lumbar region, became severe enough to necessitate operation. A tumour the size of a large nut was removed from the broad ligament, and was found on microscopical examination to have the characteristics of an endometrioma. In the second case the patient had complained of indigestion for three years, particularly at her menstrual periods, with vomiting and lumbar pain. Appendicectomy, together with the removal of the left adnexa, was carried out, and a small cystic nodule was felt in the pouch of Douglas but was not removed owing to adhesions. A year later this tumour had grown and was adherent to the posterior vaginal wall and the adjacent tissues. There were symptoms of tenesmus and some menstrual irregularity. A posterior colpotomy was performed, which gave access to the tumour. It was found to be an endometrioma, but was too adherent to be removed. Two tubes of radium were inserted, and a month later menstruation became normal, the symptoms disappeared, and the size of the tumour began to decrease. The origin of these tumours is discussed and the various theories which have been put forward are considered. The method of treatment must vary according to the localization and fixity of the tumour, the age of the patient, and the risk of injuring the reproductive organs.

Pathology

103 Simple Blood Sedimentation Test

STEIGER (*Münch. med. Wschr.*, June 11, 1937, p. 939) points out that the blood sedimentation test has proved its value in the discovery of pathological processes even when there is no clinical evidence. Its technical difficulties according to the standard methods are great, and the test cannot be performed in practice. He suggests a simple modification which gives fairly accurate results. An ordinary blood pipette graduated up to 100 mm. is used. Sodium citrate solution, 3.8 per cent., is drawn up to the 25 mm. mark and then blown on to a watch glass. The patient's finger is cleansed with ether and blood taken with a needle. The blood is drawn into the pipette up to the 80 mm. mark and then mixed with the citrate solution by blowing it in and drawing it up again into the pipette. When the blood has been thoroughly mixed with the citrate solution it is drawn up to the 100 mm. mark; a small bubble of air is allowed to remain at the tip of the pipette, and the end is sealed with candle grease or collodion. It is then hung up and the sedimentation value read off at the end of an hour. A fall of 10 mm. is normal, of 20 mm. increased, and a greater fall is pathological. The advantages of this method are that it can be performed quickly in any surgery during the routine examination of the blood, it requires no elaborate preparation, is accurate in its results, and can be used frequently during the course of an illness to estimate prognosis.

104 Weil-Felix Reaction

A. P. DE RODA (*J. Philipp. Isl. med. Ass.*, 1937, **17**, 147) has made some interesting observations on the frequency of Weil-Felix reactions in the Philippines. Blood serum from 500 febrile cases was tested against *Proteus* OX 19, OX 2, and OX *K*. Altogether 256 sera agglutinated one or more strains in a titre of 1 in 100 or over. Of these, 209 (82 per cent.) reacted at 1 in 100 to 1 in 200, while forty-seven (18 per cent.) reacted at a titre of 1 in 500 or over. The highest titre observed was 1 in 5,000. Most of the cases had been diagnosed clinically as typhoid fever or influenza. The author regards those sera agglutinating at 1 in 500 or over as coming from undoubted cases of typhus fever. A considerable proportion of sera agglutinated more than one type of *Proteus* X. Thus, of the forty-seven sera agglutinating one organism to 1 in 500 or over, ten agglutinated OX 19 only, two OX 2 only, twelve OX *K* only, fifteen OX 19 and OX 2, four OX 2 and OX *K*, and four OX 19, OX 2, and OX *K*, the titre to the second or third organism being 1 in 100 or over. Of the forty-seven typhus cases, thirty agglutinated *B. typhosum* to a titre of 1 in 50 or over. These findings are of importance in showing (1) the existence of previously unrecognized typhus fever in the Philippines, (2) the high titre required in the Weil-Felix reaction before a positive diagnosis could be made, and (3) the frequency with which more than one type of *Proteus* X was agglutinated. The typhus fever, it may be added, was of a benign type; only three of the forty-seven cases died.

105 Diabetes Insipidus

G. MONASTERIO and M. LUCARELLI (*Rass. Fisiopat. clin. terap.*, April, 1937, p. 205) record their observations on four cases of diabetes insipidus in patients aged from 18 to 47. Besides some considerable changes in the metabolism of water and salts, which are characteristic of the disease, a disturbance of the glucose regulation, occasionally of the lipoid exchange, and rarely of the energy exchange, may take place. The functional disturbance of the diencephalo-pituitary system is not limited to the regulation of the hydrosaline exchange, but it may also involve the regulation of other exchanges, especially that of glucose. The assemblage, in a very narrow space, of the centres regulating the various exchanges and of the secretion of the different hormones from a single gland, the hypothesis, so closely connected anatomically and functionally with the diencephalon, account for the fact that the disturbances of the exchanges in diencephalo-pituitary syndromes are usually more or less complex.

106 Kahn and Meinicke Reactions

A. S. AZZI and A. DEL FRADE (*Arch. Soc. Estud. clin. Habana*, March, 1937, p. 187) made a study of the relative sensitiveness of the Kahn (standard), Meinicke (M.K.R.II) and Sellek Frade modification of Meinicke's test in 100 congenital syphilitic children. Positive results were obtained in 19 per cent. of the Kahn tests, in 19 per cent. of the Meinicke tests, and in 95 per cent. of the Sellek Frade modification of the Meinicke test. In seventeen cases concordant results were obtained with all the tests. Of the seventy-seven cases in which the Sellek Frade reaction was positive, forty-three showed probable evidence of syphilis, while the remaining thirty-four were apparently normal. This is perhaps due to the fact that congenital syphilis in Cuban children at the present time is of an attenuated character, and the severe forms described in the textbooks are rare.

patient's respiration becomes regular and deep. This is misleading to a beginner, who may imagine that it indicates the automatic breathing characteristic of the third stage of anaesthesia already described. The only reliable guide to the onset of anaesthesia is the change in respiration to irregularity and/or stertor—a change which is certain to take place if air leaks are absent. The operation may be started at this point, and thereafter the anaesthetist alternates between "air" and "rebreathing" in such proportion as to avoid the convulsive bilateral twitching which indicates a commencing jactitation on the one hand and purposeful reflex movements on the other. Slight cyanosis is usual when anaesthesia has become established, but depends upon the type of patient. An anaemic girl may actually jactitate without any colour change; while a plethoric alcoholic may be almost black before reaching the stage of unconsciousness. The eye signs, although usually stressed, are so variable that in my opinion they are best ignored. The blood pressure is always raised during the administration of gas and air owing to the inevitable partial asphyxia which accompanies it.

Nitrous Oxide and Oxygen

The induction of anaesthesia is effected with pure gas until just before the "end-point" previously described. Oxygen is then added to the gas in accordance with the requirements of the individual patient. It must be realized that some degree of anoxaemia will be present in the normal subject unless fairly heavy premedication or basal narcosis has been used. When this is the case, however, it should be possible to keep most patients at a continuous level of quiet anaesthesia with little or no cyanosis. Opinions differ as to whether a slight degree of cyanosis is detrimental to patients with a normal haemoglobin value provided that the airway is clear. Respiration is fairly deep with the usual technique of partial rebreathing, but if complete rebreathing with CO_2 absorption is adopted respiration resembles that of natural sleep, and a very perfect anaesthesia can be secured. The corneal reflex will be brisk throughout the administration, and the blood pressure will be either normal or slightly raised if appreciable anoxaemia is present. Complete muscular relaxation cannot be obtained with pure nitrous oxide and oxygen unless some type of local analgesia is added or recourse is had to "secondary saturation." The latter technique will not be described here as it is unsuitable for the general practitioner, and necessitates an apparatus capable of inflating the lungs instantly with oxygen under pressure.

It must be realized that there is a very narrow margin with pure gas and oxygen, and a mixture which is slightly too rich or too poor in oxygen will eventually cause retching or actual vomiting. The beginner will find that he requires the help of a small quantity of ether added to the gases, but as his experience increases this necessity diminishes, with consequent benefit to the patient. If complete muscular relaxation is imperative sufficient ether is added to secure it, in which case the patient will show the signs of a semi-closed ether narcosis.

Ethylene and Acetylene

Ethylene-oxygen anaesthesia resembles nitrous-oxide-oxygen anaesthesia except that muscular relaxation is better and a rather higher percentage of oxygen can be used. The same remarks apply to acetylene. Since these gases are seldom employed for anaesthesia in Great Britain they will not be discussed further.

Cyclopropane

Owing to its high cost cyclopropane is always given by the closed-circuit technique, quite a simple apparatus being adequate. This gas is an extremely potent anaesthetic, and approximately 85 per cent. oxygen can be administered. Good relaxation can be obtained with this mixture, so that cyanosis should never occur. The second stage of anaesthesia is usually unnoticeable, the induction being rapid and smooth. Since cyclopropane causes no irritation and is a respiratory depressant it is easy for the inexperienced anaesthetist to give an overdose. In this case the breathing becomes imperceptible, but a few compressions of the rebreathing bag and the addition of oxygen soon restores normal rhythm. The blood pressure usually rises, and vascular oozing from the skin and superficial tissues is increased. A careful watch should be kept on the pulse, and if there is a pronounced degree of bradycardia, tachycardia, or arrhythmia the gas concentration should immediately be reduced.

Ethyl Chloride

Ethyl chloride is usually employed as a "single-dose" anaesthetic of short duration for children, and may be given by the open or closed methods. Although the child may show apparently little change for the first few moments, actually the induction of anaesthesia is extremely rapid, and the third stage may be reached within a few seconds of the cessation of talking or moving. Muscular spasm, particularly laryngeal and masseteric, may be marked in the second stage, especially if air is limited, as in the closed technique. In order to prevent clenching of the jaw an oral prop should be inserted before administration. Directly respiration becomes quiet and regular the mask should be removed, and a variable period of anaesthesia will ensue. It is possible to supplement the dose of ethyl chloride from time to time, but it is difficult to maintain an even level of anaesthesia for long, and it is extremely easy to give an overdose.

Open ethyl chloride is also useful to induce anaesthesia in children, a change-over to ether being made directly respiration becomes quiet or stertorous. Ether must be used freely at this stage, or the child will come round from the one drug before being anaesthetized with the other, in which case there will probably be coughing.

Di-vinyl Ether

Di-vinyl ether is extremely volatile, and is best given with oxygen in a closed inhaler or added in minute amounts to mixtures of nitrous oxide and oxygen. Induction is rapid, and the drug differs from di-ethyl ether in being about four times as potent, less irritating to the respiratory passages, and less likely to cause nausea and vomiting. Muscular relaxation is variable, but usually good.

Di-ethyl Ether

Induction of anaesthesia with open ether is a lengthy and trying procedure for both patient and anaesthetist. The closed and semi-closed methods, using the expired carbon dioxide to stimulate respiration, reduce the induction period considerably, especially if nitrous oxide or ethyl chloride is administered at the beginning. Even so, the second stage is apt to be marked, particularly in robust and alcoholic males. When the plane of surgical anaesthesia is established with open ether respiration becomes quiet and rather deep, the colour is pink, and the blood pressure slightly raised. Salivation and the secretion of mucus may be troublesome unless an adequate dose of

atropine or scopolamine has been given at least half an hour before induction. If good relaxation is essential the anaesthesia must be progressively deepened until the laryngeal muscles are paralysed, unless previous cocainization has been performed. After this level is reached the anaesthesia can usually be lightened appreciably. Although there is a large margin of safety with di-ethyl ether it causes an appreciable metabolic upset, as shown by raised blood-sugar and blood-urea values and post-operative albuminuria.

Two curious manifestations are occasionally seen during ether narcosis. A mild and innocuous tremor may occur during the initial stages. This generally disappears as anaesthesia becomes deeper. The more serious ether spasm is as a rule confined to the stage of deep narcosis and begins in the face muscles, ending as generalized epileptiform convulsions. The cause remains obscure, and if the usual remedies fail to stop the twitching, calcium gluconate should be injected intravenously.

Chloroform

Some degree of analgesia is common in the first stage of chloroform narcosis; the second stage is not so marked as that of ether, and there is less tendency to laryngeal spasm. The danger period of primary cardiac failure has been proved to be at the end of the second stage, just before full surgical anaesthesia is reached. A "pre-fibrillation phase" can often be demonstrated at this point by the electrocardiograph. For some imperfectly understood reason there appears to be little risk of primary cardiac failure in parturient women. Since chloroform is a respiratory depressant and does not appreciably irritate the air passages, the third stage is marked by quiet and shallow respiration. Salivation is usually absent and muscular relaxation is excellent. The blood pressure is somewhat lowered. The pupil is small and tends to become larger and inactive in overdose, while it becomes larger and active with a positive corneal reflex if anaesthesia gets lighter. The movement of swallowing may accompany these signs. The margin of safety is much smaller than with ether, but in true overdose the respiration fails first and allows time for restorative measures to take effect before secondary cardiac failure develops. Chloroform is an extremely toxic drug, and can cause grave metabolic changes. Chloroform-ether mixtures will cause deeper respiration in proportion to the amount of ether present, but it should be noted that they give no immunity from the risk of primary cardiac failure.

CHEAP MILK FOR MOTHERS AND CHILDREN

DEPUTATION TO MINISTRY OF HEALTH

SIR KINGSLEY WOOD, who was accompanied by Mr. ROBERT BERNAYS, Parliamentary Secretary to the Ministry of Health, received on July 27 a deputation from the Children's Minimum Council to urge that milk should be provided for nursing and expectant mothers and children under school age of working-class families at 1½d. a pint, and that the milk should be free where the family income fell below a scale to be determined by the Ministry. This "positive milk policy" was referred to in a leading article in the *British Medical Journal* of July 17 (p. 121).

Policy of Children's Minimum Council

MISS ELEANOR RATHBONE, M.P., introducing the deputation, said that it was supported by twenty-nine societies, including nearly all those working for child welfare. Health authorities were unanimous as to the great need for increased milk drinking, especially by mothers and young children. The great obstacle was the high price of milk. The deputation proposed that the cheapened supply asked for should be secured by diverting some of the milk now sold for manufacturing purposes at about 5½d. a gallon. Producers and distributors should be asked to supply milk under the scheme at a lower price than that now charged in the retail trade. The remaining deficit should be covered by a subsidy which, on a basis admittedly hypothetical, might amount to about £1,600,000 per annum. The Minister was reminded that a scheme roughly on these lines had been submitted three years previously, but though sympathetic consideration was promised no practical advance had been made.

Mr. C. S. ORWIN, Director of the Agricultural Economics Research Institute of Oxford, said that the recent survey issued by his institute had been quoted as belittling the probable effects on consumption of a reduction in price. The survey showed that the price of milk was of great importance, but also that ignorance of its food value and prejudice were deterrent factors. A propagandist and educational campaign was most important and should therefore accompany any scheme for a supply of cheap milk.

The Minister's Reply

Sir KINGSLEY WOOD said in reply that he was in full agreement with the main objects and the general aim of the deputation. The Government's general policy was to ensure a maximum supply of milk for the consumer consistent with a reasonable remuneration to the producer, to improve the purity of the milk supply and also to continue and, where practicable, extend their policy of increased consumption of milk among those sections of the population for whom it was of particular value.

Milk was one of the most valuable of human foods, particularly in the diet of mothers and young children. It was largely on that account that the milk-in-schools scheme had been inaugurated, and it was satisfactory that over two and a half million children were participating in it to-day. Sir Kingsley Wood said in pursuance of this policy he had recently called the attention of local authorities to the recent report of the Advisory Committee on Nutrition, and particularly to its recommendations as to the nutritional value of milk. They had been requested to review their arrangements for the supply of milk and food to expectant and nursing mothers and young children, and their special attention had also been drawn to the importance of a sufficient supply of milk being made available throughout pregnancy and for children up to the age at which they entered school. The authorities were responding to these suggestions, and a number were already extending their provisions. It was to be noted that at the beginning of 1937 406 of the 418 maternity and child welfare authorities in England and Wales were supplying milk either free or at less than cost price in necessitous cases to expectant mothers, 406 to nursing mothers, and 404 to children under 5 years of age. Closer supervision of the nutrition of children was also being secured by the provision of more nursery schools and nursery classes.

Under the recent revision of the Government grants to local authorities increased money had been made available to them for the improvement of their services, those whose needs were the greatest receiving increased assistance from the extra five million pounds which was now available. The Minister also desired to add that he attached the greatest importance to an improvement in the safety and cleanliness of the milk supply. The question of further schemes for the supply of milk, either free or at a reduced price for mothers and young children, had been under active consideration by the Government in connexion with its long-term milk policy. He could not anticipate any statement that would be made to Parliament, but he could say that the Minister of Agriculture and Fisheries still hoped that it would be possible to make a statement before Parliament rose for the recess.

ONE HUNDRED AND FIFTH ANNUAL MEETING

of the

British Medical Association

HELD IN BELFAST, JULY, 1937

THE SECTIONS

SUMMARY OF PROCEEDINGS

During the next few months there will be published in the BRITISH MEDICAL JOURNAL *the opening papers communicated to the Scientific Sections of the Annual Meeting at Belfast. The reports of discussions, continued from last week (p. 240), are intended to give members who were not present a general idea of the proceedings.*

SECTION OF MEDICINE

Thursday, July 22

Cholecystitis

With the President, Professor W. W. D. THOMSON, in the chair, a discussion on cholecystitis was opened by Professor J. W. MCNEE, who claimed that disease of the gall-bladder was the commonest of all organic troubles of the digestive tract. Piersol of Philadelphia had found that gall-bladder disease was diagnosed in 16.3 per cent. of patients admitted to a gastro-enterological clinic. Cholecystitis was by no means confined to middle-aged women who had borne children, but might occur in young men and women, and even children. A sedentary occupation causing biliary stasis undoubtedly conduced to infection, which would be due usually to streptococci, coliform organisms, or occasionally *B. welchii*. From a diagnostic standpoint the opener was concerned essentially with catarrhal cholecystitis. He felt that a history of flatulent dyspepsia, even without abdominal pain or tenderness, was significant; but he considered that *x*-ray evidence was an unreliable basis upon which to found a diagnosis in early cases. On the other hand duodenal intubation was a method of great importance; failure with this method was sometimes due to the use of the wrong type of tube, and to inexperience; properly used, it was often the only certain means of establishing the diagnosis. Professor McNee held that medical drainage of the gall-bladder could be secured by the administration of small quantities of concentrated magnesium sulphate solution before breakfast. He did not think that restriction in diet was advisable, apart from the prohibition of cooked fat and fried foods, which often aggravated the flatulent dyspepsia.

Sir ARTHUR HURST emphasized the frequency of gall-bladder disease by stating that as many patients were treated for this at New Lodge in the last ten years as were treated for gastric and duodenal ulcers combined. He was convinced that infection of the gall-bladder arose through ascending infection of the bile duct; such a method of infection would be favoured in any condition, such as gastric influenza or food poisoning, that produced temporary achlorhydria and consequently a multiplication of bacteria in the duodenum; in pregnancy achlorhydria was not uncommon, and the association with cholecystitis was well known. Sir Arthur stressed Murphy's sign as an important diagnostic test, and he shared Professor McNee's view that the cholecystogram might give little help in certain cases of catarrhal cholecystitis. He insisted that examination of the bile in suspected gall-bladder disease was as important as examination of the urine in investigating renal conditions. Bile from a morbid gall-bladder would contain excess of mucus, while microscopical examination would reveal columnar cells in groups and leucocytes in the more severe infections; pigment granules and lipoid globules might be seen, and the presence of large but broken cholesterol crystals was pathognomonic of cholecystitis. Culture revealed *B. coli* most frequently. On treatment, the speaker quoted Venables's results, which showed that the bile flow produced by oral magnesium sulphate was almost as great as that by intubation; besides magnesium sulphate on waking, he advised the administration of a tablespoonful of olive oil before each meal, and the use of hexamine in doses of 100 grains t.d.s., the urine being previously rendered alkaline and kept so during the treatment, which should continue for six weeks.

Sir DAVID WILKIE (Edinburgh) doubted whether data founded on culture of bile could be accepted. He considered that cholecystitis was a "slow, indolent, intramural, blood-borne infection"; at operations he had taken cultures from the bile, the wall of the gall-bladder, and the cystic gland, and had found streptococci in many cases, but *B. coli* in few. The indications for surgery were: (1) repeated biliary colic; (2) colic with continuing dyspeptic symptoms; (3) acute obstructive cholecystitis; (4) the suspicion that *B. welchii* infection was present; (5) gall-bladder disease at later ages; (6) stone in the common duct; and (7) when the gall-bladder was a probable septic focus for some other condition. His mortality statistics from operations for cholecystectomy and cholecystostomy were below 2 per cent. and 5 per cent. respectively. In referring to findings at operation, Sir David mentioned the frequency of associated gall-bladder disease and duodenal ulcer.

Radiology of the Gall-bladder

Dr. T. GARRATT HARDMAN (Dublin) referred to cholecystography as an outstanding advance in the diagnosis of gall-bladder disease; he did not consider the test was infallible, but with care in administration and radiological technique it was possible to make correct inferences in a high proportion of cases. It was necessary to make a complete *x*-ray investigation of the alimentary tract whenever clinical findings were at variance with those of cholecystography. This method was not only of help in diagnosing inflammation of the gall-bladder but also in determining the presence of stones, and sometimes benign or malignant growths. *X* rays might be proved fallacious when a normal picture was followed by the discovery of a pathological organ at operation; occasionally no filling was obtained, and yet a healthy gall-bladder was found at laparotomy. This might be due to deficient liver function, rapid emptying of the gall-bladder, failing of absorption of the dye, or vomiting soon after taking dye. In Dr. Hardman's experience confirmation of radiological inferences had been forthcoming in 88 per cent. of cases.

Cardiac Pain in Gall-bladder Subjects

Dr. CHARLES MILLER described the clinical syndromes in which cardiac pain might be associated with gall-bladder lesions. A sense of dying was sometimes experienced in cases of distension of the gall-bladder, and this symptom, as well as recurring anginal pain, might be relieved by suitable operation. He had made a study of the morbid anatomy of the cardiovascular system in patients suffering from non-malignant gall-bladder disease. Statistical examination of his figures had shown that there was a special liability for the subjects of gall-bladder disease between the ages of 50 and 60 to suffer cardiovascular degeneration, while for males alone the same was true between the ages of 40 and 70.

DR GEORGE BATTEN commented on the number of patients with gall-bladder disease who remained symptomless for many years. He also asked what treatment should be adopted when stones and symptoms due to them recurred after operation. DR. JOHNSTON (Westmorland) felt that his experience had brought him more and more in favour of surgery, and he described some cases bearing on operative treatment. DR. G. E. NESBITT (East London, S. Africa) agreed that intubation had its difficulties, and inquired regarding matters of technique. He threw doubt on the relation of the gall-bladder to cardiac symptoms, and also on the connexion between cholecystitis and migraine.

DR HAROLD COOKSON (Bournemouth) considered that there was less shock in acute gall-bladder syndromes than in coronary thrombosis, and that in the former group the pain might disappear suddenly. Possibly there was a reflex mechanism connecting the gall-bladder and the heart analogous to the coronary constriction that might occur in pulmonary embolism. DR. L. E. ACOMB (Newport, Mon.) mentioned the diagnostic importance of scapular pain, particularly if it was aggravated by stooping. He was rather doubtful about the value of radiology. DR. N. E. WAYFIELD (Great Bookham) considered that pain in the region of the liver might be due to transient hepatitis from the ingestion of fat foods. DR. CRAIG asked how *B. welchii* infection might be suspected before operation.

DR. J. S. MCKELVEY (Saintfield, Co. Down) commented on the frequency of gall-bladder trouble in the young, who were inclined to hurry their meals and eat too much. Belladonna and hydrated magnesia formed a good combination. DR. E. R. CULLINAN agreed that duodenal intubation was most important for diagnosis. As to the association with migraine, he thought it was doubtful whether this or cholecystitis was the primary trouble. Very often attention to the gall-bladder would bring relief from migrainous attacks.

SIR DAVID WILKIE answered several questions that had been put. Although a single stone in the common duct was associated with jaundice, multiple stones might not be. He thought that so-called bilious attacks had nothing to do with the gall-bladder.

PROFESSOR MCNEE, in conclusion, mentioned that the end of the duodenal tube should be pyriform in shape, with the blunt end foremost. The diversity of opinion regarding the infecting organism might possibly be due to the stage at which cases were being investigated. Perhaps coliform organisms related more to early infections. He thought that there were no medical remedies equal to magnesium sulphate and olive oil, and he still felt sceptical as to the value of hexamine.

SECTION OF SURGERY

Thursday, July 22

Preceding the main discussion a series of short papers were read.

Duodenal Regurgitation

PROFESSOR J. R. BRAITHWAITE (Leeds) enlarged on some points in duodenal regurgitation. He said that while physiologists had noted and investigated bile regurgitation they had done little in regard to pancreatic juice, which probably formed 80 per cent. of the regurgitant fluid. Gastroscopy was proving beyond doubt not only that duodenal regurgitation did occur, but that it was more frequent and copious than had been supposed. Bile represented only 10 per cent. of the fluid, the chief constituent being pancreatic. He was obsessed with a theory that regulation of bile might have beneficial effects on [illegible] and had at times performed cholecystduodenostomy in these cases. The results had been gratifying, but in many cases recurrence had taken place after eighteen months, when the anastomosis had been found to be closed. Re-anastomosis was as successful. If he could rely on a patent anastomosis he would advocate the operation for duodenal ulcer without stenosis, but, because of the incidence of carcinoma, he advocated partial gastrectomy for gastric ulcer. He had been talking about an operation in which bile regurgitation only was employed; he had not had the courage to divide the duodeno-jejunal junction, close both ends, and perform a posterior gastro-enterostomy, the only procedure which would allow complete duodenal regurgitation. In conclusion Professor Braithwaite asserted that duodenal regurgitation could no longer be considered an accidental phenomenon, but was well worthy of serious and widespread investigation.

Treatment of Severe Burns

PROFESSOR A. K. HENRY spoke on factors in the successful treatment of severe burns based upon findings at the Kasr-el-Aini Hospital, Cairo. Regarding the basic treatment as the application of a 5 per cent. aqueous solution of tannic acid, he emphasized the necessity of cleaning the surrounding healthy skin; otherwise sepsis often appeared at the edges of the crust. He employed a 1 per cent. solution of brilliant green in 30 per cent. alcohol, but owing to the rate of retraction of the crust, even within an hour or two, it was necessary to repaint frequently. In the treatment of the associated shock he had at one time waited for sufficient improvement before instituting the local tannic acid treatment. So many had died that, wearying of this attitude, he had set a limit of one hour. Whatever the state then the tannic acid was applied, and he had had the satisfaction of seeing many patients recover who otherwise, he was sure, would have died. In regard to the toxaemia of burns, it had been found that the blood in some of these cases contained four times the normal amount of histamine and that this increase did not occur till the fourth day after the accident, the most dangerous period where initial treatment has been successful. He associated the histamine increase with the increase of acid in the gastric juice. Massive doses of soluble alkali had given strikingly good results.

Steinach Operation for Prostatic Symptoms

MR. J. G. YATES BELL, in a paper upon the Steinach operation for the relief of prostatic symptoms, said that Niehans had ligatured the vasa efferentia between the testis and epididymis and claimed to produce an increase of the internal secretion of the testis and a diminution in prostatic hypertrophy. The theories underlying were: first, as claimed by Niehans, an endocrine effect, and, secondly, a vasomotor reflex due to the pressure of the ligature on a sympathetic ganglion. He, Mr. Yates Bell, because of late beneficial effects in two cases, subscribed to the former theory. Niehans had claimed to have relieved nearly 400 patients by ligature without much mention of failure or case selection. Elliot Smith reported good results in a small series of advanced prostatic cases, with, however, some failures. The speaker had done the operation in twenty-eight instances, in seven of which, however, other surgical procedures, such as litholapaxy, were involved, so that in only twenty-one cases was the uncomplicated operation performed. Of these fifteen were successful, two were doubtful, and four were complete failures. The greatest successes were in the cases of early obstruction. The majority of these had already had medical treatment without success. He thought the indications for the operation were: (1) in slight cases to prevent further enlargement, (2) early cases with residual urine under four ounces but established symptoms, (3) as an accompaniment of some such procedure as litholapaxy when the stones are associated with prostatic hypertrophy. The contraindications, he considered, were: (1)

established prostate cases where delay would involve risk of damage to renal function, and (2) patients with atrophic testes. He pleaded for careful case selection.

Cutting of Sphincter of Oddi for Relief of Pain

Professor E. W. ARCHIBALD (Montreal) spoke upon section of the sphincter of Oddi for relief of pain following cholecystectomy and recurring pancreatitis without stone and for subacute cholangitis. He said that following the demonstration that the direct passage of bile to the pancreas because of an impacted stone in the ampulla of Vater produced pancreatitis, he had assumed, because of the large number of cases of acute and chronic pancreatitis which were unassociated with stones, that the same theory of retrojection of bile might hold, due to spasm of the sphincter of Oddi. Later he realized that mere distension of the common bile duct and gall-bladder by spasm of the sphincter could cause pain. Where attacks of pain occurred after removal of the gall-bladder, in the absence of signs of organic cause, they would be explained by the common bile duct failing to take up back pressure as well as with the help of the gall-bladder. Where signs of organic cause were not present he advised, first, medical treatment consisting of frequent feedings and the exhibition of bile salt tablets. If this failed operation was indicated. At operation search should be made for organic causes; none being found, the procedure was section of the sphincter of Oddi. He demonstrated an instrument which, passed down the common bile duct, elevated the sphincter so that it could be got at through a half-inch incision in the duodenum.

Obstructions of the Common Bile Duct

With Professor P. T. CRYMBLE, President, in the chair, the discussion on obstructions of the common bile duct was opened by Professor E. R. FLINT, whose paper appears in this week's *Journal* at page 253.

Mr. HOWARD STEVENSON (Belfast) emphasized that in these cases one was dealing with a widespread disordered metabolism, and endorsed Professor Flint's advocacy of pre-operative preparation. Regarding drainage of the common duct, he was much more in favour of external than internal drainage, because of its decompression effect and because of the ability to introduce a tube for immediate feeding into the duodenum. Where internal drainage was instituted he had a distinct objection to the use of rigid instruments, and preferred weighted gum-elastic probes.

Mr. G. GORDON-TAYLOR, after paying a tribute to Professor Flint's work in this field, declared his almost entire agreement with the opening remarks. He, however, disliked high spinal anaesthesia in these cases; in his experience such had been associated with too high a rate of chest complications. Mr. Gordon-Taylor deprecated the growing tendency to explore the common bile duct where there was no reason for this in simple cholecystectomy. Such an additional operative step not only added to the risk but entailed additional discomfort to the patient. In the matter of suture or drainage of the common duct after choledochotomy his bias was towards external drainage, especially in obese patients. He recalled two cases in which the duct had been carefully sutured after a negative exploration, but the suture line had burst open on straining after several days. Mr. Gordon-Taylor referred to the frequent association of *B. welchii* with gall-stones and pancreatitis. He advocated the use of cyclotropin in cases of common duct obstruction associated with infective cholangitis and pre-operative irradiation of the splenic area to diminish the tendency to bleeding. In conclusion, he thought that more courage was required in dealing with malignant disease of the common bile duct, particularly at its lower end, the most common site.

Professor A. H. BURGESS (Manchester) agreed with Mr. Gordon-Taylor that choledochotomy for diagnostic purposes was too often done. In the absence of an indurated pancreas the hepatic and common ducts could be adequately palpated between the forefinger introduced into the foramen of Winslow and the thumb in front of the small omentum. After choledochotomy he invariably instituted external drainage.

Mr. NORMAN C. LAKE said that Professor Flint's mention of arthritis prompted him to postulate that the gall-bladder was a commoner site of focal infection in the abdomen than any other organ, although most cases of osteo-arthritis were of a wear-and-tear nature rather than infective. He declared a preference for high spinal analgesia.

Professor C. F. M. SAINT (Capetown) said that a likelihood of bleeding could be detected by a rising bilirubin content of the blood, and that a delayed sedimentation rate was similarly informative. He advocated the use of a Murphy button in cholecyst-enterostomy as allowing of better haemostasis. The PRESIDENT described a case of obstruction of the ampulla due to an adenoma in which local excision gave a good result.

SECTION OF PHARMACOLOGY AND THERAPEUTICS

Thursday, July 22

Treatment of Circulatory Failure

At the second session of the Section of Pharmacology and Therapeutics, including Anaesthesia, Professor DAVID CAMPBELL, Vice-President, occupied the chair.

Dr. J. CRIGHTON BRAMWELL (Manchester), in opening a discussion on the treatment of circulatory failure, compared the variations in the cardiac reserve in healthy individuals with those in patients suffering from heart disease. In the latter, while the basal disability was determined by the structural lesions, additional impairment of cardiac function was consequent upon toxic and nervous causes. He suggested that the term heart failure should include angina, and he pointed out that the general indications for the treatment of angina of effort and of congestive heart failure were the same. He contrasted the clinical features of right and left ventricular failure, and described the three principal manifestations of the latter condition—namely, paroxysmal dyspnoea, gallop rhythm, and pulsus alternans. Rest and skilled nursing and, above all, early diagnosis were the fundamental considerations in the treatment of acute heart failure. When convalescence was complete the patient's future activities should be carefully regulated in order to prevent a further breakdown. While avoiding all sudden and severe forms of exertion, he should be advised to take regular exercise within the limits of his tolerance. Stair climbing should be eliminated and special precautions taken in the event of intercurrent infections, since these added greatly to the burden of the damaged heart. The associated anxiety factor should not be forgotten, and cerebral depressants were valuable drugs for the treatment of the nervous aspect of the condition. Dr. Bramwell was inclined to regard the major surgical procedures at present in vogue for the treatment of heart failure as still in the experimental stage, but he was convinced of the value of venesection both in acute pulmonary oedema and in acute cases of congestive heart failure. In ischaemic heart failure the basal disability was dependent upon disease of the coronary arteries, but much could be done to relieve the impairment of myocardial efficiency produced by nervous and toxic factors and to lighten the additional load due to obesity and other complications. The object of treatment was to enable the heart to balance its budget by increasing its assets and by reducing its liabilities.

Professor K. D. WILKINSON (Birmingham), discussing the effect of digitalis, said that this drug was the most

THE SECTIONS: SUMMARY OF PROCEEDINGS

valuable of all in the treatment of heart failure. It might prevent and would generally alleviate this condition, and it should be given in adequate doses to all cases of congestive failure whatever the rhythm of the heart. The best preparation for oral administration was the powdered leaf in doses of 1 to 4 grains a day, but strophanthin or digoxin 0.25 mg. might be given intravenously in emergency. It might be necessary to give one of the preparations in large doses so that speedy control of a failing rapid heart might be established, but the very necessity for such action suggested that an impending case of heart failure had not been recognized. In these circumstances 6 grains of the powdered leaf could be given at once, a further 3 grains in six hours, and another 3 grains within the first day. Or if the condition was more urgent 0.25 mg. of strophanthin or digoxin could be given intravenously and repeated in two hours. The average daily dose of leaf needed to control the ventricular rate in fibrillation was about 3 grains, but much less might be adequate and much more might be necessary.

Dr. S. B. BOYD CAMPBELL (Belfast) said that peripheral failure could be treated by increasing the blood volume and the chloride deficiency by intravenous injections of saline with or without glucose or by transfusion of whole or citrated blood. In the collapse associated with thyrotoxicosis the addition of collosol iodine and calcium gluconate to the injected saline was often useful. Digitalis was of limited value in peripheral failure, but strychnine, caffeine sodium benzoate, and adrenaline could be prescribed with advantage. Regarding the treatment of oedema, Dr. Campbell said that he had found the newer mercurial diuretics of considerable value. A satisfactory diuresis could be produced by the use of novurit suppositories when injections were not tolerated. Acupuncture was useful in cases of generalized oedema, and this could safely be performed by making fifteen to twenty small punctures down the front of each leg. The risk in tapping the abdomen was slight, but great care must be taken when tapping the chest in cases of heart failure.

Dr. A. R. GILCHRIST (Edinburgh) said that dietetic measures were a subsidiary but important aspect of the treatment of many forms of heart disease. The heart could be regarded as a sensitive index of the degree of nutrition as witnessed in such extreme states as war oedema and anorexia nervosa on the one hand and in obesity on the other. An excessive calorie intake was much the more common, and treatment for obesity was of the greatest importance in cardiac patients, particularly in those with anginal symptoms. In congestive heart failure rest was promoted by a low caloric diet, and help was obtained by restricting the daily intake of fluid to about one litre. A low salt intake was also of value in certain types of congestive failure, for this reduced thirst and facilitated drug action. Dr. Gilchrist suggested that, in congestive failure, disorders of inorganic metabolism in the periphery could not be disregarded, and he believed that attention to this aspect by restriction of salt and fluid played a useful and important part in treatment.

DR F. P. POULTON said that, when there was evidence that pulmonary oedema was associated with weakness of the heart in general, efficient oxygen treatment was of great use. This form of therapy was also of value in arteriosclerotic heart disease rather than in the valvular disease of young subjects. The closed method of administering oxygen by a closed tent was more efficient than open methods such as Campbell's mask and the double nasal tube and catheter. With the closed type of tent it had been shown that an oxygen figure of 40 per cent. could be obtained with a flow of 11 litres per minute, and that this could be increased to 50 per cent. with a flow of 12 litres per minute. With the St. George's Hospital type of tent, however, it had been shown that, with a flow of 6 to 8 litres per minute [illegible] per cent. of oxygen in the pocket at the bottom [illegible] at the end of half an hour the percentage [illegible] was 20 to 25.

Dr. GEORGE GRAHAM referred to some observations on a patient with typical paroxysmal attacks of pulmonary oedema. The blood pressure rose soon after the onset of the attack, and the haemoglobin value rose from 80 to 135, showing a great increase in the concentration of the blood. The acute onset of the symptoms and the rise in blood pressure suggested that spasm of the pulmonary veins and *not* left heart failure was the causal condition. The symptoms were relieved by the subcutaneous injection of 1/2 c.cm. of adrenaline, repeated twenty minutes later, and he suggested that this agent should always be employed after the preliminary use of morphine. Care should be taken not to inject adrenaline into a vein.

Dr. M. ASTON KEY (Southsea) said he had found the newer mercurial diuretics to be of very great value and, for oral administration, apocynum was not without its uses. He had always found Nativelle's granules a satisfactory preparation of digitalis. Dr. A. FULLERTON (Batley) inquired if icoral or cardiazol were of value in the treatment of peripheral failure. Professor J. H. GADDUM explained that Nativelle's digitalin was a mixture of glucosides with a preponderance of digitoxin. Digoxin was prepared from digitalis lanata.

Dr. J. F. COLTMAN (Calcutta) believed that pitressin was of value in peripheral failure, and he advocated a preliminary estimation of the specific gravity of the blood before the intravenous injection of saline in order to give some idea of the quantity required. Professor CAMPBELL observed a time lag between the result of pharmacological investigation and its clinical application. He believed that a more accurate classification of cases would lead to a more accurate use of drugs.

Therapeutic Use of Magnesium Trisilicate

Dr. NATHAN MUTCH contributed a paper with this title. He said that medicinal magnesium trisilicate had been defined as a compound represented by the formula $H_4Mg_2Si_3O_{10}$, and giving the pure diffraction radiogram of the natural mineral sepiolite No. 1. The ratio $MgO:SiO_2 = 1:2.24$. It had been shown that many of the marketed brands of magnesium trisilicate failed entirely to conform to these basal requirements, mainly in respect of the $MgO:SiO_2$ ratio. This substance, which was non-poisonous, could be employed in therapeutics in order to secure continuous control of gastric acidity in hyperacid states without the production of systemic alkalosis. The silica deposited as a result of interaction between the gastric hydrochloric acid and magnesium trisilicate was free for absorption purposes in the small intestine.

Dr. POULTON said that test meals performed before and after the operation of gastrojejunostomy for ulcerative conditions showed no difference in the degree of gastric acidity, and he therefore expressed the view that a mechanical factor was mainly involved in the causation of these states. Professor CAMPBELL inquired if magnesium trisilicate gave quick and permanent relief. In reply, Dr. MUTCH stated that this drug, although it possessed potent adsorptive properties, was put forward as a means of continuously controlling gastric acidity.

COMBINED SECTIONS OF OBSTETRICS AND GYNAECOLOGY, AND NUTRITION

Thursday, July 22

Nutritional Needs in Pregnancy

With the President of the Section of Obstetrics and Gynaecology, Professor C. G. LOWRY (Belfast), in the chair, a discussion on the nutritional needs in pregnancy was opened by Sir ROBERT MCCARRISON (Oxford), Dame LOUISE MCILROY, and Dr. G. C. M. M'GONIGLE (Stockton-on-Tees), whose papers appear in this week's *Journal* at

pages 256, 258, and 259. Dr. M'Gonigle was prevented from attending, and his paper was read by Professor D. C. HARRISON (Belfast). The discussion was continued by Dr. LUCY WILLS, who dealt with osteomalacia and with the needs for calcium and phosphorus. She said that the healthy non-pregnant woman required 0.55 gramme of calcium a day, but in pregnancy the requirement was about 1.6 grammes. The diets of many women contained less even than the former figure. The needs of pregnancy could only be met by ensuring the intake of at least a quart of milk per day, together with either exposure to sunlight or the intake of vitamin D. She pointed out the frequency of occurrence of osteomalacia in pregnancy in Eastern countries, and stated that although osteomalacia was rare in this country the frequent occurrence of negative calcium and phosphorus balances led to osteoporosis and carious teeth in nursing mothers and to rickets and ill-developed teeth even in breast-fed infants.

Dr. MARGARET I. BALFOUR dealt with some practical means of securing better nutrition. She pointed out difficulties in the way of giving extra milk or extra meals to pregnant women of the poorer classes, and commented on the success of the scheme initiated by the National Birthday Trust Fund for providing vitamin supplements. The mortality among 7,000 women taking the supplements had been 1.69 per 1,000, as compared with 6.69 per 1,000 among a comparable group of 14,000 women not taking supplements. The cost had worked out at 2s. 6d. a head per month.

Sir FRANCIS FREMANTLE (Hatfield) put forward a plea for greater emphasis on the need for adequate rest in the working day of the expectant mother. Only in this way could the mother assimilate her food properly. Dr. E. H. M. MILLIGAN (Glossop) had studied the budgets of fifty-two families, and found the income per head in the family to be 4s. 6d. On this sum it was impossible to afford a quart of milk a day. Sir MANGALDAS V. MEHTA (Bombay) reported on the high incidence in Bombay of maternal mortality due to nutritional anaemia. The diet of the poorer women consisted largely of polished rice and gravy.

Mr. L. CARNAC RIVETT criticized the opener's statement that the problems of nutrition in pregnancy were the same as those of the ordinary woman. He felt that the value of milk had been much overstressed. Colonel C. H. REINHOLD, I.M.S. (Punjab), claimed that there was more than one dietary factor involved in the production of osteomalacia.

Professor A. LEYLAND ROBINSON (Liverpool) thought it was wrong to say that the nutrition of a pregnant woman was the same as that of a non-pregnant woman. The presence even of an early foetus made a profound difference to metabolism. It was a great mistake to attempt to treat early toxaemias of pregnancy by partial starvation. Professor LOWRY said that there was nothing lacking in the vision of the medical officers of health, but they were often hampered by the committees which controlled them.

Sir ROBERT MCCARRISON, in closing the discussion, felt that the goal to be aimed at was the rearing of healthy women who could take pregnancy in their stride. Ultimately the crux of the problem of nutrition was an economic one. Dame LOUISE MCILROY stressed the element of neurosis due to household worries in the development of vomiting of pregnancy. It must not be treated by starvation, and fluids must be pressed.

Vitamin E in Habitual Abortion

Mr. D. W. CURRIE (Leeds) read a paper on the use of vitamin E in the treatment of habitual abortion. He reviewed the experimental evidence which had led up to the clinical tests. Some people have said that the vitamin is only necessary in the first three months of pregnancy. In his own series the results had been very good, although most of his patients had not started taking the vitamin until after the third month. They had been given 3 minims daily of wheat-germ oil, and only women who had had two abortions previously were considered in the result. Thirty-seven women, who had had only fifteen viable children out of 121 pregnancies, after treatment gave birth to thirty-six children with only three abortions and four deaths after birth.

Food Intakes of Pregnant Women at Different Economic Levels

Dr. R. A. MCCANCE, in a paper on the actual food intakes of pregnant women at different economic levels, said that in the past most studies had related solely to family diets. It was very difficult to calculate the actual intake of individual members of the family from these family figures. He and his colleagues had weighed the actual intake of each food constituent in the daily diet of pregnant women. He had studied three economic groups in which the income per head in the family after deduction of rent had averaged respectively 8s., 14s., and 26s. 5d. In every respect there was a progressive improvement in the intakes over the three groups. The intake of milk, calcium, and phosphorus was well below the recommendations of the League of Nations Report, even in the highest economic group. He had no political axe to grind, and put the figures forward as a basis for scientific consideration of the problems of nutrition.

SECTION OF DISEASES OF CHILDREN

Thursday, July 22

Dilatation and Elongation of the Colon

With Dr. H. MORLEY FLETCHER, President, in the chair, a discussion on dilatation and elongation of the colon was opened by Professor J. R. LEARMONTH (Aberdeen), the text of whose paper was published in the *Journal* of July 24 (p. 154).

Mr. F. A. R. STAMMERS (Birmingham) pointed out that surgeons in operating upon the abdomen for various conditions had many opportunities of observing anatomical variations in the arrangement of the intestine, and yet in none of these instances did these patients necessarily or commonly suffer from constipation. Hence if the neuromuscular mechanism was physiologically normal it probably did not greatly matter what the shape or length of the bowel was. If diet or defective hygiene led to constipation, however, then some anatomical abnormality of the large bowel might aggravate the resultant constipation. Mr. Stammers pointed out that the milder degrees of dilatation of the colon might not be accompanied by constipation at all, and it was the increasing size of the abdomen which caused patients to seek advice. With reference to the neurogenic factor in the causation of megacolon the speaker mentioned two examples of disorders affecting the lumbosacral region of the cord followed by dilatation of the colon. Accepting the theory of the neurogenic origin of megacolon, he continued, he employed section of the sympathetic nerve supply when medical means had failed. He thought the best operation was to expose the upper part of the presacral plexus, and dissect out and remove fibres ascending from this up to the inferior mesenteric artery and surrounding it for about one inch. Mr. Stammers summarized the results in eight patients thus treated, the youngest of whom was operated upon at the age of 1 year. He thought that patients requiring operation were usually less than 5 or 6 years of age, and on the whole the earlier in life operation was performed the more likely was cure to result, because there would be less change in the wall of the bowel.

Dr. T. PEARSE WILLIAMS emphasized the embryological double origin of the colon in relation to the function of

the distal colon as a storehouse for waste matter. Elongation of the large bowel was usually confined to this portion, the sigmoid loop remaining in later life what it was normally in the infant. This elongation might be the only determinable factor in some cases of constipation, and the type of constipation which occurred was prone to be associated with definite abdominal symptoms, especially colic. French writers, said Dr. Williams, had named the condition "dolichocolon," but not every long colon was associated with constipation, nor was every constipated child the owner of a long colon. Nevertheless, in his opinion unexplained constipation in young children should be investigated radiologically both by an opaque meal and by an opaque enema. Treatment should be non-surgical, and should be by means of diet, habit control, and physiological laxatives.

Dr. ROBERT MARSHALL (Belfast) asked what purgatives or laxatives were best employed in the conditions under discussion, and also what exactly was the best sort of diet to order. *Mr. G. D. McFADDEN (Belfast)* raised the question of the actual effect of the sympathetic and parasympathetic nervous systems upon the movements of the distal colon. In his experience section of the sympathetic nerve supply did not produce an emptying of the colon, but more frequently a moderate degree of atonic dilatation. He agreed as to the importance of through-going barium meals. Professor JOHN MORLEY (Manchester) pointed out how surgical opinion of the subject of anatomical variations in the large bowel in relation to symptoms had changed in recent years. He thought that what mattered much more was training in the earliest weeks of life. In true megacolon the effects of sympathectomy were dramatic, but he had considerable misgivings about the permanency of results. Professor L. J. WITTS asked what happened to children with megacolon who were not operated upon. He commented upon the inefficiency of the average radiological technique in examination of the bowel.

Sir ARTHUR HURST (Windsor) explained his views on the development of megacolon as a result of achalasia of the anal sphincter. Certain later developments might lead to an apparent kink at the pelvi-rectal junction, but he was now convinced that this was not a separate entity. Radiological examination should be made in the erect posture, and Sir Arthur agreed as to the importance of an opaque meal as well as an enema to get a true picture of the conditions present. He was opposed to surgical measures, treating his patients by dilatation of the anal sphincter. In early cases this was sufficient, but occasionally an "air-lock" in the upper part of the pelvic colon might occur, and operations to remedy this state of affairs might be necessary. Dr. ROBERT HUTCHISON deprecated so much investigation of cases of constipation, especially if surgery was now held to be seldom indicated for enlarged or elongated colon. He thought that many of the abnormalities in childhood were outgrown, but volvulus might occur if there were redundant loops of bowel present. The PRESIDENT described the termination of certain cases of megacolon with diarrhoea and coma.

Scarlet Fever

Professor SEYMOUR BARLING (Birmingham), Vice-President, took the chair, and Dr. W. R. F. COLLIS (Dublin) read a paper on the modern control of scarlet fever. He thought that the present terminology was misleading, for tonsillitis with erythema was called scarlet fever, and pharyngitis (caused by the same streptococcus) without a rash was regarded as a mild complaint for which no special measures were undertaken. Isolation of cases of clinical scarlet fever for six weeks did not stop the spread of the disease, and in a recent school epidemic Dr. Collis had attempted to follow the course of all cases by means of throat swabs. He thought that control of scarlet fever, including pharyngitis caused by the haemolytic streptococcus, should be by means of throat swab [illegible].

Dr. A. GARDNER ROBB (Belfast) was against the use of throat swabs, and stated that he was more alarmed by the problem of nasal infection. Dr. J. D. ROLLESTON also protested against a bacteriological conception of scarlet fever, and he did not approve of swabbing throats of scarlet fever patients before discharge from hospital.

Cleft Palate

Mr. W. E. M. WARDILL (Newcastle-upon-Tyne) read a paper on cleft palate. He explained his approach to the operation, holding that functional results were all that mattered, and he had devised his operation so that the child then grew up naturally without after-training in speech. His procedure consisted essentially in narrowing the nasopharynx. Gramophone records were played to demonstrate the speech results obtained.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE

Thursday, July 22

Mental Effects of Head Injury

The second session was presided over by Professor LAMBERT ROGERS (Cardiff), when the subject for discussion was the mental manifestations of head injuries.

Professor E. MAPOTHER confined himself for the most part to problems of incidence and diagnosis. There was, he said, a great dearth of reliable information about the probable future course of head injury cases, and there were no figures for the amount of consequent mental disorder. The Board of Control statistics had, however, revealed no clear evidence of any rise in mental disorder in spite of the increase in road casualties. In military medical circles there seemed to be a conflict of opinion: some had claimed a rise in the incidence of psychosis following head injuries in warfare, while others had found very little trouble of this kind. There was a similar disagreement in reports from other quarters. Both psychosis and schizophrenia of psychiatric form were probably traceable to head injuries. Statistics from a group of mental hospitals south of the Thames pointed to an incidence figure of about 3 or 4 per 1,000; this was probably an underestimate, since many psychotic patients in whom the symptoms were not very troublesome were kept at home. In 5,000 private patients mental disorders had been traced to head injuries in 123 instances; ninety-two of these were undoubtedly of traumatic causation, and the remainder were probably so. The mental irritability after an accident was of doubtful pathogenesis, but constituted an important factor in prognosis. Professor Mapother thought that post-traumatic psychosis represented the last of a series of stages of degeneration of mental function. In traumatic psychasthenia there was some weakness of the higher mental states; the patient was detached from the outer world, and his internal mental mechanism was affected.

Dr. J. PURDON MARTIN approached the neurological aspect of head injuries by detailing the mental symptoms in various classes of cases and their physical accompaniments, and discussing their physiological nature and the pathological changes. He defined "unconsciousness" as the lack of conscious memory, but pointed out that the recovery of memory might often be very gradual, the patient remaining amnesic with regard to a variable period before the accident. Mental activity was at first low, and the early improvement was sometimes of the nature of conditioned reactions. Confusion and disorientation as regards time were frequent, especially when subarachnoid haemorrhage had occurred. Physical activity might be fully restored long before spontaneous mental activity had regained the normal in all respects. After being irritable, resentful, and abusive, the patient often became elated and childishly happy as the result of frontal lobe disturbance.

and this elation persisted for weeks or months, masking an anxiety state. The general tendency was for such mental symptoms to progress towards recovery within six months with some residual symptoms. In some cases, however, partial recovery was followed by dementia, especially in those aged over 55. Subarachnoid haemorrhage was the most likely cause of many symptoms. The degree of meningeal haemorrhage was an important causative factor. Traumatic neurasthenia was an unfortunate term for many cases of receding dementia with a basis in cerebral injury. True neurasthenic symptoms might be superimposed on a clinical picture of slight persisting dementia, but the prognosis was generally good. Gross hysterical manifestations after injury usually resulted from pre-existing tendencies in persons of poor mentality, but might be symptomatic of a degree of persisting traumatic dementia; minor manifestations might have an "escape" significance. Sometimes the injury seemed to precipitate an attack of depression in a patient whose mental constitution was of the cyclothymic or manic-depressive type.

Dr. F. E. PILKINGTON suggested a few lines of psychiatric treatment. He condemned the *laissez faire* attitude as being as bad as indiscriminate therapeutic activity. There were still persistent symptoms several years later in patients discharged as cured, so the present cheerful attitude towards prognosis could not be justified, especially since elation was common in the convalescence of head injury cases. Treatment in an ordinary medical or surgical ward was undesirable, as was also the environment of a mental hospital ward. One member of the medical team should be a psychiatrist, or the patient should be removed to a voluntary psychiatric clinic. Prolonged rest should never be synonymous with neglect—actual, or even imagined by the patient. Adequate sleep must be secured, by hypnotics if necessary, and the luminal group was useful; bromide treatment was especially dangerous in arteriosclerotic cases. The fear of becoming insane was not uncommon. Suitably designed reassurance might be very valuable, even when there was obvious organic damage. Compensation hysteria was a purely psychogenic phenomenon with a purposive objective, and it seemed to be becoming more common. It should be treated by a final lump sum settlement after the diagnosis had been complete and accurate.

Dr. H. HILTON STEWART (Belfast) discussed the mental changes in children. He offered a classification of groups according to the symptoms and the organic changes. In compensation hysteria the symptoms were often suggested to the children by the parents. The explanation of behaviour changes was far from clear, but some organic factor often unmasked a personality abnormality due to the environment. The evidence was sometimes difficult to elucidate, but it ultimately became clear and satisfying. The family background was an essential field for exploration in cases of head injuries in children. Mr. C. E. WINTERSTEIN said that boxing might have neurological and psychological sequels. Here compensation hysteria could be excluded. In fifty treated cases the consequences had been classifiable as: (1) the immediate ones after a single punch; (2) the remote effects of repeated injuries. In the first group a knock-out had been followed by loss of reflexes and amnesia; the latter might be strictly limited to the event, but retrograde amnesia varied in length. Sometimes also there might be an anterograde amnesia extending over the period when normal activities had been resumed for a long time. A post-traumatic state of this kind was not uncommon in head cases generally. The speaker contrasted this with the symptoms in trunk injuries ("punch drunkenness"), but mental dullness was commoner in patients of low intellectuality, who were more susceptible to punch drunkenness than were those with more sensitive temperaments. The cause of punch drunkenness was repeated multiple injuries; the syndrome was not progressive, and decreased when boxing stopped.

Dr. W. RITCHIE RUSSELL (Edinburgh) remarked that the phenomena of concussion originated from a jarring of the tissues of the brain affecting conductivity, but not demonstrable pathologically. Transient cerebral anaemia was probably not so directly associated. Crushed head injuries were often not followed by loss of consciousness. This jarring might be more severe in more serious accidents, and nerve elements be severed thus. Slight impairment of the higher cerebral functions was a common post-traumatic finding in minor accidents. Very young children who had just begun to speak retrogressed in this respect about six months after a head injury or encephalitis; this was due to impairment of vulnerable cortical control centres in early life. Some permanent impairment of the higher cerebral functions was much commoner than was generally supposed, and ought to be more carefully considered in assessing the after-effects of severe head injuries. The duration of retrograde amnesia was another important point. Dr. Ritchie Russell doubted whether cerebral irritability was so often due to subarachnoid haemorrhage as had been stated. Dr. JOHN THOMPSON (Belfast) held that more cognizance ought to be taken of interference with the blood supply to the cerebral cells, especially in elderly persons. This condition probably caused many symptoms, including the emotional changes.

Mr. W. MCADAM ECCLES pleaded for care in the use of terms in the law courts. Unconsciousness was a term hard to define. Could it be acknowledged as the condition when a person who had had a head injury did not realize what was happening around him? "Fits" might be much less than those of epilepsy, but they should not be lightly disregarded. Dementia should not be lightly mentioned, since it appeared to be looked upon as most serious and to preclude recovery. Traumatic neurasthenia was a very real condition to the patient, and often to his friends, but it was probably true that it dated from lack of proper early treatment of the head injury, often only a slight one, and maintained by the delay, often legal, in settlement of the claim. It was necessary, therefore, to be clear, decisive, and full of common sense in dealing with the mental effects of a head injury.

Dr. R. G. GORDON (Bath) said that in the lesser mental effects very obvious symptoms were mental inactivity and easy fatigability. These symptoms were probably due not to gross or even pathological changes such as could be seen at post-mortem examination, but to biochemical changes at the synapses analogous to those in the peripheral nervous system in myotonia. If success were ever reached in finding a method of estimating such central synaptic changes, a pathological interpretation of the symptoms might emerge. In children there were often obsessive phobias, but in some of these cases there was a neuropsychic habit fostered by the anxiety of the parents. It was important to remove these by early psychotherapy; otherwise, by accretions of other emotional experiences, they might become permanent obsessions. Sir E. FARQUHAR BUZZARD (Oxford) dealt with anterograde amnesis. He related a personal incident of a football accident which had been followed by loss of memory for the remainder of the match. He added that retrograde amnesia might provide some measure of the severity of a concussion. Professor A. A. MCCONNELL (Dublin) referred to some statistical evidence which had been forthcoming, and touched on the post-mortem evidence in these cases. He concluded that the question of prognosis would often be very difficult. Professor ROGERS thought that cerebral oedema was a very important consideration, and referred to a series of cases dealt with at Cardiff. Treatment by general dehydration of the body by magnesium sulphate had proved to be most effective.

Replying to the discussion, Professor MAPOTHER emphasized the importance of schizoid psychoses as common sequels of head injuries. He referred to the question how far the actual organic damage was related to the subsequent mental symptoms, and concluded that such relation was very small. In many cases gross injuries had given rise to few psychological sequels, and slight injuries to serious ones. Much turned on the previous life and

mental outlook of the victim. Amnesia was an extremely complex state. Retrograde and traumatic amnesias might be largely a matter of the patient being unwilling to think. The spread of popular psychology had much to do with the victims of accident cases complaining of loss of memory. Dr MARTIN agreed that dementia was a most unfortunate term in this connexion and that it would be better to speak of traumatic psychasthenia. In head injuries the emotional state (elation) differed from that which was found in vascular lesions of the brain.

SECTION OF OPHTHALMOLOGY

Thursday, July 22

Squint and Heterophoria

With the President, Mr. J. A. CRAIG (Belfast), and subsequently Dr. P. J. HAY (Sheffield) in the chair, Mr. W. H. McMULLEN opened a discussion on squint and heterophoria, with special reference to orthoptic treatment.

After reviewing the historical development of the subject he discussed the current theories on the causation of squint. The fact that concomitant squint frequently came on after acute illnesses had been used to support the view that squint was of muscular origin, either as a congenital weakness exaggerated by the illness, or perhaps as an acquired condition similar to post-diphtheritic paralysis. But all the evidence was against squint being due to a paresis of muscle, and, furthermore, in an obvious congenital or a very early squint paresis of muscle does not lead to constant squint. The accommodation theory advanced by Donders found its support in the often-repeated observation that squinters had high hypermetropia. None the less there were squinters with myopia, and not all hypermetropes were squinters. As recently modified the emphasis in this theory was on excessive convergence; this produced separation of the two images, and so helped by suppression to overcome diplopia. The view steadily gaining ground was the one which saw squint as a defect in vision faculty. It might, however, be held that the lack in binocular vision was the result and not the cause of squint, for in orthoptic clinics it was often found that good binocular vision gained by training could rapidly be lost in cases of persistent heterophoria. Moreover, cases with good fusion faculty were occasionally seen. Anisometropia had been blamed by many observers; but here again binocular vision might be present in spite of a high degree of this defect. The significance of heredity was assessed differently by different observers, and was intimately linked with the question of the nervous factor. In fact, some cases of squint fell within the province of the psychiatrist. The influence of environment was admitted by most observers; the affection seemed to be commoner among the poor. No agreement was yet possible on the question of the relation of amblyopia to squint. There was much evidence to support the view that amblyopia arose *ex anopsia*, but the possibility of macular haemorrhages in infancy could not be ignored. The recent developments of orthoptic training had a long history, going back quite clearly to Javal, and perhaps earlier to Roux in 1814. One point of significance that had emerged from the latest work was that squint training was possible at a later age than that which Worth had considered the upper limit, the age of 6 probably being the ideal. Mr. McMullen concluded with an account of the development of the orthoptic clinic in the Royal Westminster Ophthalmic Hospital and the reasons for the establishment of an Orthoptic Board.

Concomitant Squint

Mr. G. G. PEARSON followed with a paper on general considerations in the treatment of concomitant squint. He said that orthoptic training could not as a rule be undertaken in the case of children under 4 years old, nor in those of [illegible] mentality. Vision in the poorer eye had to be no less than 6/18, and the refraction fully corrected in all cases. Occlusion of the better eye was a valuable procedure, and in his exerience only less than 10 per cent. of squinters with amblyopia failed to recover sufficient sight to fit them for orthoptic training. He discussed the different methods of occlusion, such as the use of atropine in mild cases, and stripping the correcting lens, the Chavasse glass, the Doyne occluder, and adhesive plaster, in the more severe forms. Before orthoptic treatment could be usefully undertaken abnormal retinal correspondence had to be eliminated; where this could not be achieved orthoptic treatment would not help, just as it would fail where there was complete lack of the fusion sense and marked incomitance or vertical deviation. Generally forty-eight sittings were given, but the cases had to be kept under observation afterwards, as some required supplementary treatment. Good cosmetic and functional results could be expected in over half the cases by orthoptic treatment, which, incidentally, had raised the criteria of success. He considered that a standard method of recording results was most desirable, and submitted a scheme of his own.

Problems in Squint Training

Miss MURIEL A. PUGH, in discussing some problems in squint training, said that there were more unsolved problems in squint training than was usually admitted. Although squint cases could be trained to a considerable degree of binocular vision, it was often found that one eye remained dominant, and that this dominance was due not to a difference of visual acuity, but to the ratio of light values. The exophoria group exhibited the dominant eye, which also showed a parallelism between the lateral and vertical deviation—different in kind from the relation of hyperphoria to lateral phorias in the concomitant squints. Vertical phorias presented most difficulty. There seemed to be more than one type, and it was often difficult to assess the origin and history of the trouble. She held that special orthoptic clinics and expensive apparatus were not necessary for the treatment of many of the simple squints with true projection, and for the heterophorias which were likely to react to exercise. Simple stereoscopes used with the specially designed charts to correct either esophoria or exophoria, and the careful use of vertical prisms in the stereoscope in the cases of hyperphoria which were likely to react, gave as good results as more elaborate instruments, which were essential in cases of complicated deviation or marked defect in the binocular vision.

Heterophoria in Binocular Disharmony

Wing Commander P. C. LIVINGSTON read a paper on the role of heterophoria in binocular disharmony, with special reference to air pilotage. He classified heterophoria as symptomless and symptom-producing; either might be inherent or acquired. The one great cause of inherent heterophoria was dominant macular reception; where rivalry was present symptoms developed. Acquired heterophoria might come on at any period in life. He held that the part played by heterophoria in the induction and maintenance of a psychological state was not emphasized enough. Of the symptom-producing phorias heterophoria and exophoria with weakness of convergence were the most important with regard to air pilotage. He stressed the significance of the development of heterophoria as a result of prolonged fatigue from concentrated flying, from tropical asthenia, from malaria, or from head injury. Heterophoria thus produced did not tend to persist once the primary cause had been removed. These cases were generally those of inherent heterophoria becoming manifest under strain. One had to avoid the mistake of trying to develop a theoretical ideal; inherent heterophoria with dominant macular reception should be treated by an attempt to overcome a manifest phoria. Treatment of symptom-producing phorias always required a complete survey of the patient's mental framework. Orthoptic training was valuable as part of this scheme,

but it constituted a part only. The paper was illustrated by films bringing out the difficulties met with in flying.

In the discussion that followed Mr. J. D. M. Cardell suggested that measles and whooping-cough might produce squint through a lesion of the fusion centre, and that in other cases aniseikonia might have a bearing on the aetiology. Mr. W. B. Inglis Pollock (Glasgow) said that the avoidance of amblyopia involved early treatment by training or operation. Mr. R. Affleck Greeves discussed the general factor in squint, and believed that nasopharyngeal sepsis tended to be overlooked. Mr. N. Bishop Harman emphasized the more critical and confident attitude of the modern outlook on squint. He held that the correction of heterophoria was one of the most grateful tasks in ophthalmology. Mr. D. D. Stenhouse Stewart (Hull) discussed acquired heterophoria, and instanced cases of its disappearance after the removal of an exciting cause. Dr. T. Stewart Barrie (Glasgow) thought that whilst orthoptic treatment had a definite place, its value was limited by the age factor and the necessary selection of material. Mr. J. W. Killen (Londonderry) pointed out the dangers involved in too radical operative disturbance of the extra-ocular muscles. Mrs. Beatrice H. Lynn (Belfast) and Mr. H. Caiger (Sheffield) discussed points in the technique of orthoptic training.

Ectopia Lentis with Arachnodactyly

Miss Euphan M. Maxwell (Dublin) reported in detail a case of ectopia lentis associated with arachnodactyly. Her patient, a boy of 10, showed typical skeletal changes, a miotic pupil, subluxated lens, and extrasystoles. She discussed the theories of arachnodactyly, and drew attention to the view that arachnodactyly and other mesodermal syndromes have a common underlying factor (see *Journal*, July 3, p. 22). Her paper was illustrated by lantern slides.

Mr. Arnold Sorsby drew attention to the development of acute glaucoma in such cases owing to dislocation of the lens into the anterior chamber. Lieut.-Colonel R. E. Wright, I.M.S., stressed the unsatisfactory operative results in this complication. Mr. J. A. Corkey (Belfast) gave details of a family with arachnodactyly under his care. Dr. E. J. Primrose (Glasgow) emphasized the partial character of the syndrome in some cases.

COMBINED SECTIONS OF RADIOLOGY AND PATHOLOGY

Thursday, July 22

Bone Tumours

With the President of the Section of Radiology, Dr. J. C. Rankin, in the chair, Dr. R. E. Roberts (Liverpool) opened the discussion on bone tumours with a plea for the orderly interpretation of films. He had devised a scheme that included a list of changes in structure and in contour of bones in diseased conditions, which he submitted to the meeting. Most innocent tumours, such as chondromata and traumatic osteomata, had typical radiological appearances. Some malignant conditions were also typical, but many were very difficult. Dr. Roberts showed a large number of films illustrating these points, together with case histories. Biopsy, he thought, was often misleading, and *x*-ray treatment helped in the diagnosis in many cases. He had purposely avoided reading his original paper, which would be published later, and had confined himself to the demonstration of films.

Professor J. S. Young (Belfast) speaking of the responsibilities of the pathologist, said that at the Royal Victoria Hospital, Belfast, open biopsy was a routine in all doubtful bone tumours. Many workers were violently opposed to this. It was essential to diagnose bone sarcoma before it metastasized. If radiography failed to make a sure diagnosis only two procedures remained—serial radiography and biopsy. Biopsy might increase the risk of dissemination of tumour cells, but, by the delay involved, serial radiography involved a similar risk. Bone tumours grew under mechanical restraint, and it was fair to assume that the hydrostatic pressure was higher than in soft tissue tumours. When haemorrhage occurred this pressure increased, with further danger of forcing tumour cells into the vascular channels. He thought that the hydrostatic pressure was more important in this respect than vascularity. He regarded Hoffmann's method of biopsy as 100 per cent. dangerous because of the haemorrhage which took place within the growth. Open biopsy was attended by no rise in pressure. Wood's experiments with rats showed that open biopsy was not attended by increased liability to metastasis. Of the seventy-four five-year cures in the American Registry of Bone Sarcoma no fewer than twenty had been subjected to biopsies, curettages, explorations, and excisions. The microscope was an instrument of much greater precision than the radiographic machine. Serial radiography and the radiodiagnostic test were dangerous because of the delay involved. In every case which could possibly be a bone sarcoma, open biopsy should be performed.

Mr. Harry Platt (Manchester) was unable to be present, his paper being read by Mr. H. O. Clarke (Manchester). Diagnosis of bone tumours, he said, should be based on history, clinical signs, *x*-ray changes, and biopsy. Responsibility for diagnosis and treatment rested entirely with the surgeon. Bone tumour cases should all be dealt with at special clinics because of the comparative rarity of such cases. The dangers of biopsy were mythical, and it was a valuable aid to diagnosis. He performed the operation under a tourniquet, cauterized the deeper part of the wound, and closed the capsule. All bone tumours should be removed surgically. Certain early giant-cell tumours should be curetted and others excised. Amputation should be performed in sarcoma of long bones, combined with *x*-ray treatment of the chest and Coley's fluid.

Dr. J. F. Brailsford (Birmingham) said that the clinician was becoming increasingly anxious to pass the responsibility of diagnosis on to the radiologist. In spite of a negative Wassermann reaction bone lesions might be syphilitic. The radiodiagnostic test was not dangerous unless the surgeon refused to intervene when radiation treatment failed. He thought biopsy was dangerous, since release of pressure caused more rapid growth. Less than 5 per cent. of the American cases survived ten years, and this was such a low proportion that he thought here was room for error. Histology might be misleading, sometimes because material was removed from the wrong place. The radiologist should be consulted about this. Necrotic neoplastic material might be mistaken for pus. Dr. Brailsford showed several films of cases in which the radiologist had been proved right and the surgeon and pathologist wrong.

Professor M. J. Stewart (Leeds) thought that immediate biopsy (frozen sections) was unfair to the pathologist, who had to give a far-reaching decision in a few minutes. The sections were never so good as paraffin sections. Different pathologists sometimes gave various opinions on the same section. Even the benign giant-celled tumour was sometimes difficult to diagnose; in order to be sure the matrix must not be unduly cellular, and the giant cells must be widely and uniformly distributed. Mr. F. C. Pybus (Newcastle-on-Tyne) said that in 1929 he had acquired a pair of mice of the Simpson strain, which was prone to develop mammary carcinoma. In one of the descendants a sarcoma of the sternum had occurred, and he had succeeded in producing a strain which was liable to osteoplastic bone sarcoma. They developed metastases in the lungs, liver, spleen, and kidney. The advantage of this animal experimentation was that it provided ample material in the case of a disease which was comparatively rare. He proposed to investigate the causal factor in these mice.

Mr. Stanford Cade recalled that seventeen years ago, at a meeting in London, one of the speakers summed up

the question of bone sarcoma by saying that all the patients died. Since that was so the danger of biopsy was a negligible factor. The difficulty about biopsy was that it often failed to make a diagnosis in otherwise doubtful cases. He disagreed entirely with Mr. Platt and Dr. Brailsford, and thought that both diagnosis and treatment of bone sarcoma were primarily radiological. If radiation failed surgery should be used. There should be a panel of skilled pathologists to whom sections in bone sarcoma cases could be submitted. Surgical measures rarely cured bone sarcoma or delayed the onset of metastases. Prophylactic x-ray treatment of the lungs was useless because when metastases later appeared in the lungs it was impossible to deal with them. At the Westminster Hospital all cases were treated by *x* rays or by radium beam therapy, or by both. Calcium in large doses should be administered to all cases.

Mr. R. C. ELMSLIE congratulated Dr. Roberts on his schedule. He thought, however, that increased calcification and decalcification were misleading terms, as was osteitis fibrosa. He agreed with Professor Young that biopsy should be done and a large piece of tumour removed. Immediate biopsy was unfair to the pathologist. Benign giant-celled tumours should always be treated surgically. He agreed with Mr. Cade that some form of bone sarcoma registry was necessary.

Dr. ROBERTS, in reply, said that he had included decalcification and increased calcification in his schedule because he had occasionally seen cases where those terms would apply. He thought that closer co-operation was needed, particularly between pathologist and radiologist.

Professor YOUNG, in his reply, criticized the surgeons because they sometimes removed tissue which was not representative of the tumour and blamed the pathologist for the result. He disagreed with Mr. Cade about the treatment of bone sarcoma. All except one of the cures in the American Registry were treated surgically. Dr. Brailsford had said that relief of pressure resulting from biopsy brought about more rapid growth. This did not matter, since surgical removal would be undertaken at once. He regarded Dr. Brailsford's tendency to speak in terms of radiopathology as dangerous. He thought that histopathology was much more reliable.

SECTION OF TUBERCULOSIS

Thursday, July 22

Surgical Treatment of Apical Cavities

With Dr. A. TRIMBLE (Belfast), a Vice-President, in the chair, Dr. CARL SEMB (Oslo) opened a discussion on the surgical treatment of apical tuberculous cavities.

In the treatment of pulmonary tuberculosis thoracoplasty meant first and foremost cavity therapy. It should achieve: (1) complete collapse of the cavity; (2) selective collapse of the diseased part of the lung alone; and (3) the operative risk must be small—the mortality should not be greater than 3 per cent. Dr. Semb stressed the importance of accurately localizing the cavity before operation, and discussed the mechanical principles underlying thoracoplasty. He preferred the term "relaxation therapy" to collapse therapy. In performing thoracoplasty the aim should be to mobilize the lung in a manner similar to artificial pneumothorax, so as to enable it to retract concentrically towards the hilum. He described the "ordinary" methods of thoracoplasty. Even those most extensive could not in all patients produce enough collapse of cavities in the upper lobe. There were definite disadvantages, too, in combining these thoracoplasties with extrafascial apicolysis: the latter might be difficult, sometimes impossible to perform, and the collapse was not so complete. He had devised a modification with more satisfactory results. The apicolysis was carried out in the extrafascial plane, was combined with a radical rib resection according to the extent of the apicolysis, or more, and a new extrafascial space was prepared by cutting periosteum of ribs and other structures in such a manner that they were not loosened from the surface of the lung. The dropped upper lobe stayed put, instead of being "pulled" up again by the ribs later, as in extrapleural apicolysis. Moreover, no "dead extrapleural space" was left.

Dr. Semb described the technique and possible complications of his operation, and insisted on the importance of performing it in stages. He discussed the factors by which one must be guided in deciding the "size" of these stages. Evulsion of the phrenic nerve should not be done previous to a thoracoplasty. It increased the risk of post-operative complications. It might, however, give effective collapse when carried out afterwards. His results of the operation in over 250 patients since 1932 were: mortality within two months, 6 per cent.; dead later, 5 per cent.; complete collapse (as judged by radiography) in 90 per cent.; and tubercle bacilli disappeared from the sputum in 86 per cent. The results were even better since 1934, when he began using systematically small and several stages: among a total of 149 patients the mortality within two months was 3 per cent.; dead later, 3 per cent.; radiological complete collapse in 93 per cent.; and disappearance of tubercle bacilli in the sputum in 91 per cent.

Mr. J. E. H. ROBERTS agreed that many surgical procedures used at present did not give complete collapse of the cavity. An artificial pneumothorax often produced a collapse that was not selective, though it completely collapsed the cavity. These cases were sometimes not satisfactory also because the lung remained adherent at the first dorsal vertebra—when the lung was allowed to re-expand the cavity was apt to become patent again. He had rarely seen an apical cavity closed as the result of phrenic evulsion. The cavity had failed to close in at least half the patients treated by apicolysis and plombage. Some patients were too ill to undergo even the first stage of Semb's operation. The shock following the latter was due to the rib resection and not to the apicolysis. This was in favour of the method recently advocated—extrapleural apicolysis and maintaining the extrapleural space by the repeated introduction of air as in ordinary artificial pneumothorax. He had adopted this method in fourteen patients with encouraging immediate results. If the lung re-expanded in spite of refills, gomenol should be introduced.

Dr. ANDREW MORLAND said that in deciding what cavity demanded surgical collapse the probable mode of origin of the cavity must be considered. Where there had been extensive destruction of lung tissue spontaneous healing was less likely than in those cavities in which the inflation element predominated. Artificial pneumothorax should always be tried first. It might succeed in the most unhopeful-looking cases. His own experience with apicolysis had been most unfortunate. There could be no doubt that a cavity constituted a much greater danger to life than a thoracoplasty. It was important to choose the right time to operate. Dr. Morland discussed the contraindications. Tuberculosis elsewhere was not necessarily a contraindication. He thought that a preliminary phrenic evulsion might assist in resting the lung, and render the patient fitter for the major operation.

Mr. GEORGE A. MASON (Newcastle-on-Tyne) stressed that each case required treatment on its merits. He referred to methods of the future—tying the pulmonary vein, lobectomy or pneumonectomy, and direct drainage of cavities. When section of adhesions was not possible in a contraselective pneumothorax the phrenic nerve should be paralysed—temporarily at first, for healing of the cavity was obtained in only half such cases. The dangers of thoracoplasty carried out later were greatly increased when the diaphragm was paralysed. The maintenance of a contraselective pneumothorax until the completion of an upper thoracoplasty was of definite benefit. He spoke in favour of apicolysis with plombage in suitable patients.

Dr. G. S. TODD (Midhurst) emphasized that not all cavities needed surgical treatment as soon as they were discovered. The presence of cough and sputum, and thick walls, were, however, indications for surgery. He spoke in favour of phrenic evulsion for apical cavities when they were small and thin-walled. He was not convinced of the advantages of the crush operation. The danger of basal spread after thoracoplasty in patients who had had the nerve paralysed was probably exaggerated. The results of apicolysis with plombage had been most disheartening. After Semb's operation, which took longer than the simple thoracoplasty, convalescence was much more stormy. He had seen three patients in whom as the result of the operation the cavity had been merely pushed down into the middle lobe.

Mr. H. MORRISTON DAVIES (Ruthin) also referred to the possibility of the cavity being merely pushed downwards. The comparison between the principles underlying artificial pneumothorax and Semb's operation was not quite accurate. In surgical procedures it was essential to have compression as well. In the ordinary thoracoplasty it was important to allow torsion of the costal cartilages to take place. It was therefore a wrong principle to remove too much of each rib. The transverse processes should be removed, but scoliosis should be prevented. He spoke emphatically in favour of phrenic paralysis in selected cases. Mr. G. R. B. PURCE (Belfast) said it was surprising what could be achieved with adhesion section and phrenic paralysis in patients who had an ineffective pneumothorax. Dr. L. S. T. BURRELL advocated the trial of conservative treatment before resorting to surgery. The mere presence of a cavity was not an indication for collapse treatment. Dr. BEHRENS (Davos) described the method of extrapleural artificial pneumothorax.

Dr. J. CROCKET (Glasgow) then read a paper on artificial pneumothorax, with special reference to bilateral collapse. It appears in this week's *Journal* at page 261.

SECTION OF DERMATOLOGY

Thursday, July 22

Autophytic Dermatitis

With the President, Dr. G. B. DOWLING, in the chair Dr. HENRY MACCORMAC opened a discussion on autophytic dermatitis.

Dr. MacCormac said this condition was far from uncommon, and in its various forms might deceive every class of practitioner, including dermatologists. The number of recorded cases was now considerable. By the application of various external agents, or even by rubbing the skin, it was possible to produce a variety of dermatological conditions. The appearances might mimic various skin infections. The most important guide, however, to correct diagnosis lay in their inaccuracy of reproduction of a recognized disorder. A true occupational dermatitis might be deliberately aggravated or extended at will by the patient concerned. Admission to an institution and the application of occlusive dressings would, by the rapid healing of lesions which had persisted for months or years, reveal their true nature. At other times an inspection of the patient's belongings would be rewarded by the discovery of the causal agent. Sometimes, however, these occlusive dressings appeared to aggravate the eruption, and the speaker had devised a wire cage into which a part of a limb could be inserted and locked. The individuals who resorted to these deceptions were of different patterns, falling into groups which could usually be clearly separated: (1) The hysterical group, divided into (*a*) purposeless eruptions and (*b*) purposeful eruptions; (2) the malingering group; (3) the mischief group; (4) the phantom dermatoses. Group 1 (*a*) represented the most characteristic and deceptive class. There was no apparent object to be gained, and personal appearance might be severely damaged. Patients in this group were nearly always young unmarried women. In the most severe cases submission to surgical mutilation was not uncommon. He described several cases of his own and others to illustrate some of the features observed. Group 1 (*b*) were usually women of mature age who had been, or had become, difficult or unreasonable. There was an attempt to evade unwelcome duties, with simulation of illness to gain pity. Two cases of this nature were described. Group 2 consisted of those who wished to gain a monetary or other advantage, or to avoid a disagreeable duty. This kind of deception was met with during the war, and was often very difficult to detect. Thus a piece of tinfoil stretched over the skin and multiple punctures made through it rubbed over with sand, could produce a perfect imitation of a boil. Another example was the deliberate aggravation of an occupational dermatitis by a workman long after removal from contact with the supposed irritant. It would, however, be wrong and unjust to suspect as fraudulent more than a very small minority of this class of case. Group 3 cases were usually children, who as a class often enjoyed mystifying their elders. Either this fact or the natural instinct for mimicry would probably explain the epidemics of supposed alopecia areata which had been described in certain schools. Occasionally, however, an autophytic dermatitis might be observed in a child where a spirit of mischief seemed sufficient to explain the circumstances. Every practitioner had encountered the Group 4 type of patient who complained of a rash which he (the patient) thought was obvious, but of which the unbiased observer could see little or nothing. At the consultation, in the presence of an expert, the true state of affairs was seen. Such conditions might be closely related to the phantom dermatoses where the patient's imagination inflicts an eruptive process upon the skin. These conditions were apparently a form of hallucination.

Recognition and disclosure of the true state of affairs, Dr. MacCormac said, usually raised new and perplexing problems. The dermatologist could rarely satisfactorily explain the patient's perverted behaviour to the relatives. Nothing was gained by confronting the individual with the deception. The result was always an indignant denial. It was essential to be certain before expressing an opinion, as no diagnostic error was ever more resented. He had himself investigated the after-history of eleven young women who had had hysterical eruptions. All but one had ceased to inflict lesions on the skin, and some of the replies revealed the curious fact that the knowledge of what they did had been submerged or completely forgotten.

Dr. R. D. GILLESPIE said that he defined autophytic dermatitis as a "self-inflicted lesion where the patient persisted in denying the fact of self-infliction." This excluded "reflex" scratching of existing lesions and lesions produced by fidgety manipulation. It included, on the other hand, cases in which the primary interest need not have been that of self-deception. There was, he said, no single specific psychological mechanism even in the restricted sense of his definition. The more frequent motives were the avoidance of some difficulty or the gaining of attention, with which was mingled self-pity, and sometimes also resentment and revenge. But these motives could not be understood apart from the personality and general circumstances of the patient's life. In the group of neurotic personalities, especially the hysterical, the inner needs of the patient were of outstanding importance, and there might be little or nothing in the external circumstances to help to explain the condition. The suggestion that the lesions were inflicted in a "dissociated" state of mind usually had slender evidence to support it, even where there was a history of hysterical fits or similar phenomena. In one case of this nature evipan semi-narcosis proved useful in eliciting facts which had previously been withheld. In another group the lesion represented the "resolution" of motives—that is, it achieved

a compromise between the compulsive desire to inflict injury on another and self-punishment for this compulsion. In a further group the chief motives were exhibitionistic and erotic. In many of these cases the nearest relatives might be either reluctant, or even openly refuse, to accept the proper diagnosis. It might then be necessary to carry conviction to this quarter before the patient would cease to inflict self-injuries.

The PRESIDENT asked, What was the ultimate prognosis in these cases? In reply Dr. MACCORMAC said that complete recovery was usual. Dr. W. G. HARVEY (Dublin) doubted if trichotillomania was really a single entity. He thought that in some cases it might result from intolerable itching. Patients with exceptional vulnerability of the skin might present special difficulties—for example, cases of eczema or epidermolysis bullosa. Dr. H. R. FREDERICK (Port Talbot) described a case in which the hope of financial compensation seemed to be the most important factor. Dr. R. T. BRAIN mentioned the common forms of artefact lesions (excoriations, bullae, necroses), and referred to the difficulty in discovering the noxious agents employed. In two of his cases these had proved respectively to be smelling-salts and a blistering fluid contained in an old eau-de-Cologne bottle. Dr. MASON BOLAM (Newcastle) said that out of 17,000 new patients who had attended the Royal Victoria Infirmary in the last five years only twenty-five were diagnosed as suffering from autophytic dermatitis. Of these, twenty-one were females, and the average age was 19½. Dr. A. C. ROXBURGH and Dr. MCCARVILL (Dublin) also took part in the discussion.

Virus Diseases of the Skin

Dr. R. T. BRAIN, in a paper on the methods and difficulty of treating virus diseases of the skin, pointed out that in virus diseases specific therapy followed the usual bacteriological procedures, and depended upon the use of vaccines and sera. Unfortunately evidence existed which indicated that in some virus infections specific antibodies were practically ineffective when the virus had once reached a susceptible cell. Methods of producing active immunity in virus diseases were: (1) Vaccination with living virus: (*a*) human strain (for example, herpes); (*b*) with a virus modified by animal passage (for example, vaccinia); (*c*) attenuated by time or temperature (for example, rabies); (*d*) neutralized with immune serum (for example, distemper). (2) Vaccination with killed virus: heat, formalin, or phenol, and a further modification of virus absorbed on inert protein or other material. Methods of raising the antibody content of the blood in herpes by inoculation with living virus and dead vaccine were discussed, and the speaker said that some good results had been obtained. Specific therapy had been tried without any success in the case of warts and molluscum contagiosum. Some of the common non-specific methods of treating herpes, warts, and molluscum contagiosum were briefly mentioned, and reference was also made to the use of posterior pituitrin extract and sodium iodide in the treatment of zoster.

Minor Methods in Dermatology

Dr. F. A. E. SILCOCK (Leicester), in a paper on some minor methods in dermatology, first referred to triethanolamine. This was a trihydroxy-triethylamine which he thought was an agent of possible dermatological value. It was a clear syrupy liquid resembling glycerin in appearance, and had a specific gravity of 1130. It was alkaline in reaction, was almost odourless, and mixed freely with most liquids. It was an excellent emulsifier for soaps, creams, etc., and owing to its low alkalinity and resulting stability of emulsion was without caustic action on the skin. It would saponify some fats in the cold. Triethanolamine was a common ingredient of many cosmetics, and could be used advantageously in many dermatological conditions. He had found it useful in the removal of excessive horny and sebaceous material in cases of acne vulgaris or those with an oily type of skin. He described several formulae he had employed for this purpose. A piece of cotton-wool was moistened with the solution and then rubbed firmly over the affected areas for a few seconds till a thin soapy lather appeared. It was then rinsed off and the skin dried. There was only a slight temporary tingling sensation. The method was useful as an adjunct to *x*-ray treatment or as an alternative when such treatment was contraindicated. The speaker also described the use of trichlorethylene, which was not only useful as a domestic cleaner but also as a degreasing and cleansing agent. It was non-inflammable and mildly antiseptic, with a Rideal-Walker coefficient of 0.9. Dr. Silcock, in dealing with the treatment of herpes zoster, said that Head and Campbell had suggested that the pain in this condition resulted from nervous impulses passing from the posterior root ganglion in the sensory nerve. Goodpasture, however, found that it was due to the passage of the virus itself in the nerve sheath. The pain could be relieved in many of these cases by the intramuscular injection of "P.B.A." (percaine 0.5 per cent., benzyl esters 10 per cent., carbolic acid 1 per cent., in an oily base). He injected 2 c.cm. round the affected nerve; this could be repeated a few days later if required. The relief of pain sometimes occurred in a few minutes and was maintained for several days. In other cases he had found a four-fifths pastille dose of *x* rays useful when applied locally to the affected areas of skin. In the presence of vesication he used a 1/2 mm. or 1 mm. aluminium filter. He then showed several gadgets he had found useful, including a modified crochet-hook for removing the lining membrane of sebaceous cysts, some skin punches, and a small scalpel useful for the treatment of warts. He also demonstrated the use of vacuum-filled capillary glass bottles for the application of pigment solutions to local areas, and an apparatus for repeated intramuscular injections.

Dr. ROBERT KLABER mentioned two isolated cases in which ill effects had followed the use respectively of triethanolamine and trichlorethylene.

In the afternoon Dr. IVAN H. MCCAW gave a demonstration of cases and of pathological specimens in the King Edward VII Hall at the Royal Victoria Hospital. This was followed by a discussion, in which several members took part.

INTERNATIONAL SHORT-WAVE CONGRESS

[FROM A CORRESPONDENT]

The International Short-Wave Congress, held in Vienna from July 12 to 18, was an event of great interest and importance, and was attended by some six hundred doctors, physicists, and biophysicists from every country in Europe, from America, Egypt, and Japan. In three or four years of rapid development the value of short and ultra-short high-frequency currents in medicine, surgery, and gynaecology has become firmly established. In England, however, we have been strangely slow to take up this form of treatment, owing partly to insular prejudice, partly to questions of finance, and partly to the lack of medical interest in physiotherapy in our teaching hospitals.

Section of Physics

The Congress comprised three Sections: Physics, Biophysics, and Medicine. The Physics Section, presided over by Professor Esau of Jena, whose researches enabled Schliephake to evolve the principles of short-wave therapy, discussed the future possibilities of television, questions of interference, the part played by ultra-short waves in aviation, chemistry, and recent ionosphere work. The rest of the time of the section was devoted to practical

questions regarding distribution, absorption, and measurement of energy in the short-wave field and the recently invented instruments for measurement, output, and dosimetry. The generation of centimetre and millimetre and hectomicron waves by the magnetron, and the value of these waves for scientific measurement, were also discussed.

The shortest wave-length produced hitherto in America measures 6 mm., but Professor Esau has succeeded in obtaining one of 4.9 mm. The energy of these tiny waves is of course infinitesimal, but it is hoped in the near future, by the aid of certain optical instruments, to increase the output of energy ten million times.

Biophysical and Medical Section

In the Biophysical and Medical Section the three chief problems were (1) dosage, (2) specific electric effects other than that of heat, and (3) selectivity of wave-length. Two papers of much interest in this section came from the Institute of Medical Research at Frankfurt, from Professor Rajewesky, who succeeded Dessaur there, and from Dr. Schaefer. The former discussed the electrical properties of biological tissues at various frequencies, and showed the value of such measurements in revealing the microscopical structure of living tissues and in distinguishing between the normal and the pathological. Dr. Schaefer demonstrated the influence of human-cell and animal-cell structure on the energy distribution of ultra-short high-frequency currents, and both he and Dr. Pätzhold showed the dependence of depth effect on adequate spacing.

The president of the Medical Section, Dozent Liebesny, demonstrated the importance of "athermic" treatment in acute inflammations and in tuberculous conditions by films and on living patients who had suffered from various forms of surgical tuberculosis and were all cured by athermic short-wave treatment.

Section of Medicine

The Medical Section dealt with results and methods of applying short-wave therapy to acute and chronic diseases, and many papers were of great interest and value. The discussion was opened by Professor Schliephake, who laid stress on the chief indication for short-wave therapy—that is, acute inflammations and suppurative conditions in the skin, sinuses, antra, lungs, and pelvis. The secret of success in applying short-wave therapy to these conditions is mild dosage and low intensity. He considers that the improved results from this athermic treatment give another proof of the value of specific action other than that of heat.

It is impossible in this limited space to mention all the interesting papers read in the Medical Section; two were outstanding—one by Professor Wintz of the Erlangen Frauenklinic, the other by the Berlin ophthalmic surgeon Gutsch. Professor Wintz admitted that the first results of short-wave therapy at Erlangen had been disappointing owing to deficient technique, to the use of unsuitable and too long wave-length, and, above all, to the low output of the apparatus then available. With these it was impossible to attain success in deep-lying organs.

For the last two years, however, apparatus of adequate output has been supplied; great advances have been made, and the results of short-wave therapy are now so good that it has become the most important form of treatment at Erlangen. Its chief indications are acute inflammatory processes, adnexitis, parametritis, and inflammatory tumours of the adnexa, including those due to gonococcal inflammation. He finds it also of value in many conditions of endocrine failure, hypoplasia, amenorrhoea, etc., also in menopausal disturbances not due to toxic factors. This form of therapy is contraindicated in all tuberculous infections of the genital tract and in malignant disease.

Complete details of the Erlangen technique were given for both acute and chronic conditions, such as wave-length, time, dosage, the best possible couch for treatment, position of patient, etc. Athermic therapy is of value on commencing treatment of acute cases. In all chronic forms of disease, however, heat is a necessity. Everything depends on the correct technique and on accurate medical observation.

Dr. Gutsch of Berlin gave an interesting survey of 700 eye cases treated successfully in his clinic by short waves. Here again good results are obtained in acute inflammatory conditions: serpiginous ulcer and hypopyon, abscesses of orbit and vitreous, post-operative inflammations, and infected wounds. In all these conditions the results of short-wave therapy are far superior to those of diathermy in rapid relief of pain and inflammation and in the homogeneous depth effect.

The best results of all, Dr. Gutsch considered, were attained in the posterior orbit—that is, in diseases of the iris, choroid, and retina. These parts, hitherto inaccessible to most forms of local treatment, respond particularly well to short-wave therapy: the active hyperaemia, and rapid resorption of exudate and haemorrhages and oedematous swellings, are remarkable. He gave details of the technique worked out by experiment on his own eyes and those of his co-workers. Athermic treatment with the ultratherm is the rule, and the 6-metre wave-length has on the whole been found most suitable. No bad effects of any sort have been observed. His good results were confirmed by workers in Mellor's eye clinic in Vienna, where, however, apparatus of lower output—namely, 30 watts—is used for most eye conditions.

During this crowded and interesting week all the members of the congress were magnificently entertained by the Government of Austria in the beautiful castle of Schönbrunn, the home of the Hapsburgs, and also by the Mayor of Vienna at the great historic Burg of Falkenstein. The Vienna Congress of 1937 has left us with much evidence as to the properties of short and ultra-short high-frequency currents, and has given a great impetus to the future development of short-wave therapy.

A TOUR OF SCANDINAVIAN HOSPITALS

Representatives of the Westminster Hospital who left England in July at the invitation of their chairman, Mr. Bernard Docker, to visit Scandinavian hospitals had a most interesting trip. The party included Mr. J. D. C. Couper, a member of the building committee, Mr. E. Rock Carling, the senior surgeon, Mr. Charles M. Power, the secretary, and two governors, Mr. John Docker and Mr. Edward Joynson. Great hospitality was shown by Government health officials, hospital authorities, and the leading medical men of each city visited.

Visit to Stockholm

Three days were spent in Stockholm, where Sven Ahlbom, architect of a new general hospital of 1,200 beds, which will be ready for occupation in six months, showed them every detail of this building. Much time was also spent in studying, with the aid of the architect-engineer, Hjalmar Cederstrom, the plans and models of another new hospital of 1,500 beds now being built by the municipality. A morning with Professor Berven at the Radium Institute, which will be removed to the nearly completed new general hospital, revealed remarkable work done under difficult conditions. A State-aided "follow-up" system organized for cancer patients enables former patients to return for examination.

In new Swedish plans the delegates found marked resemblance to the plans for their own new hospital, especially in the matter of small wards and the out-patient scheme, which will bring out-patients and in-patients together under one administration. It was noted also that Sweden has the same problem as this country, inasmuch as there is now hospital provision for the rich and the poor, but a marked lack of provision for the middle class.

Helsingfors, Tallin, Danzig

At Helsingfors Professor Wichmann's gynaecological hospital was the chief object of interest. Professor Wichmann came back specially from Copenhagen to spend the evening discussing his hospital and the problems connected with his work. The Red Cross emergencies hospital was also inspected.

At Tallin, Estonia, an interesting private nursing home and a military hospital of 350 beds were inspected, and the visitors found in Professor Stamm a most enthusiastic surgeon and authority on hospital planning. At Danzig Professor Volthard and Professor Klose took a great deal of trouble to explain the organization of the city's hospital services. The Municipal hospitals supplied material for observation and comparison, and the visitors were much impressed by the extensive well-organized and equipped radiographic department.

Copenhagen

Copenhagen, with the inspection of four hospitals, completed the tour and provided possibly the most interesting feature of it, the orthopaedic hospital there being alone regarded as sufficient recompense for the whole of the trip. The visitors had as their guide Chief-Surgeon P. Guildal, adviser to the Danish Board of Health, who took the main part in planning this great hospital centre. At Copenhagen the visitors also saw the Finsen Institute, and found much of interest in Professor Lomholt's work and description of this organization, which now includes the magnificently equipped new radium centre recently opened by the King of Denmark.

A report prepared by Mr. Bernard Docker, Mr. Rock Carling, and Mr. Power will be available for the use of other British hospitals seeking information about the practice and equipment of the hospitals seen on this tour.

RESEARCH FELLOWSHIPS IN TROPICAL MEDICINE

The Medical Research Council, on the advice of its Tropical Medical Research Committee, has made the following awards:

Senior Fellowship.—Frank Hawking, D.M., D.T.M., assistant lecturer in pharmacology, Welsh National School of Medicine, Cardiff. This is tenable for three years, for investigations to be made mainly in the Tropics. Dr. Hawking will work in Africa on the chemotherapeutic treatment of sleeping sickness.

Junior Fellowships.—David Alexander Cannon, B.Sc., M.B., Ch.B.; John Leslie Dales, M.B., Ch.B., assistant pathologist, Royal Hospital, Sheffield; Ian Wilson MacKichan, M.B., B.Ch., house-surgeon, London Hospital. These are also tenable for three years during the first two of which the holders will undergo training in this country in tropical medicine and in the use of research methods.

The Joint Tuberculosis Council announces that arrangements have been made with Dr. W. J. Fenton, the dean of Brompton Hospital, for courses of fourteen sessions in artificial pneumothorax work, each course to extend over a fortnight. The classes will be held on Mondays at 10 a.m. and 2 p.m., Tuesdays at 10 a.m., Thursdays at 6.30 p.m., Fridays at 10 a.m., and Saturdays at 10 a.m. and 2 p.m. Included in the courses will be four lectures on the general aspects of artificial pneumothorax therapy and detailed instruction in screening. After the members of the class have had a few days' experience of the practice at Brompton Hospital they should perform the actual refills, and, if possible, an induction themselves. Each course will be limited to four members. The duration of the classes will vary with the number of cases to be dealt with, but an average of two hours is a near approximation. The fee for the course is £5 5s., and all applications should be addressed to Dr. William Brand, Secretary to the Board for Postgraduate Courses, Joint Tuberculosis Council, 5, Cavell Church Place, Epsom, Surrey.

Local News

INDIA

The Armies in India

Volume II of the annual report of the Public Health Commissioner with the Government of India for 1935, which has recently been published, deals with the health of the British and Indian Armies in India, and reveals that in both cases there was a reduction in disease. In that year the combined ratio for the British Forces of those constantly sick in hospital and under treatment as out-patients was 47.42 per 1,000 of the strength, as compared with 49.19 in 1934. The decrease in the incidence of cerebrospinal meningitis continued; triple concentrated serum was the usual treatment, but in three cases iodine was also given intravenously with complete success. The incidence of sandfly fever remains unaltered, and no good system of prophylaxis has been discovered, nor have attempts to infect mice with material from human cases and so to secure a fixed virus proved successful. It is noticeable that, both with barracks and bungalows, the majority of men occupying old buildings with mud walls invariably succumb, whereas in new or well-repaired buildings the occupants escape, provided rubble heaps and other potential breeding places in the vicinity are removed. Some caution seems to be called for in the differential diagnosis of fevers of the typhus group; this at present turns on laboratory findings and is rendered uncertain by the possibility that enteric group infections might have some influence on proteus OX agglutinins in the serum. It is considered, therefore, that at present search must be continued for the enteric group of bacilli even in the various OX positive cases, especially in those in which the disease is mild and there is no rash. Further investigations in regard to this problem of diagnosis are proceeding. An outbreak of cutaneous and faucial diphtheria in a battalion engaged on the North-West Frontier in the autumn of 1935 presented some curious features. Abrasions of the skin caused by the rocky country were found in some cases to be harbouring Loeffler's bacillus, and there was also faucial diphtheria in some though not in all. For the treatment of these cutaneous cases diphtheria antitoxin was injected intramuscularly and also applied locally as a dressing. In most instances the ulcers were healing by the fourth day, and diphtheria bacilli could no longer be recovered from them. In some, however, the organism persisted in spite of there being a healthy granulating surface and serum treatment being prolonged; the best results here were obtained by applying mucidan as a dressing. The incidence of the enteric group of fevers increased slightly in the British Forces as compared with 1934, which was the lowest on record; in the Indian Forces there has been a progressive incidence since 1932, which is only partly explained by the fact that previously some cases of typhus were included as the result of faulty diagnosis. There has been very greatly improved bacteriological investigation of these cases during the last ten years. In 1935 there were nine deaths among the British and thirteen among the Indian troops, and in nineteen of these death occurred before the end of the second week, suggesting either an overwhelming infection or an ambulant type of the disease. Both the admission and death rates in men under one year's service in India fell markedly in 1934 and 1935 as compared with men whose service had been longer, and it is concluded that this fall may reasonably be attributed to the T.A.B. vaccine manufactured at the Royal Army Medical College since 1933. The case mortality was, however, disappointingly high during 1934 and 1935, mainly owing to the type of case previously described. The percentage of cases occurring within the first six months after reinoculation has remained almost constant during a period of seven years

at just above 30 per cent., which still appears unduly high, but no explanation is at present forthcoming. The incidence of dysentery remains stationary, and reasons are given in the report for fearing that this will continue to be the case until efficient sanitary services and a sanitary conscience have been developed, not only in military establishments but throughout the country. One of the striking features of the post-earthquake period in Quetta was a dramatic fall in the dysentery incidence among the troops. For several years previously the incidence in that station had been high and was actually increasing in spite of the most stringent precautions in the military area. The fact that from 1930–5 there were 21,000 fewer admissions for dysentery among Indian troops reflected the steadily improved sanitation among them since the post-war period, but, as in the case of British troops, it is feared that the position has now become stationary. Quetta was the second worst station in respect of malaria in 1934, but headed the list in 1935 with Peshawar and Agra second and third respectively. Efforts are being made to secure more protection in the new cantonment at Quetta, but unfortunately the main breeding stations lie outside military control. Very great improvement in this respect was noted in Delhi for 1935. Since the use of plasmoquine in the Army in India became almost universal the chronic relapsing cases of benign tertian malaria have almost disappeared; this treatment is generally preceded by atebrin.

Public Health in Bombay

In his report for the year 1935–6 Dr. J. S. Nerurker, executive health officer for Bombay, states that the excess of births over deaths was unequalled before 1931, the number of live births being now the highest on record since 1866, when such statistics began to be noted. The death rate was higher than in the previous year, owing largely to an epidemic of small-pox with 402 deaths, and increases in the mortality due to respiratory diseases and tuberculosis, dysentery, measles, and cerebrospinal fever. There were decreases in respect of plague, influenza, ague, and malaria. The population of Bombay is now much in excess of the census figures obtained in 1931. The previous negligence in registering births has been overcome to some extent by the provision of maternity benefit for the labour classes, which constitute 74 per cent. of the population of the city. The death rate among infants under the age of twelve months has increased in the poorer classes, mainly in consequence of respiratory diseases and immaturity; special efforts are being made to combat this by providing municipal district nurses, attendance at confinements, necessaries and comforts during the puerperium, maternity homes, and infant welfare centres and milk depots. The small-pox epidemic was responsible for 1,248 deaths, as compared with 152 in 1934; emphasis is placed by Dr. Nerurker on the vital importance of revaccination, which at present is optional in Bombay. The figures for the attendances at venereal clinics show that the proportion of new patients having primary syphilis and acute gonorrhoea is rising. Pre-nuptial examination is also becoming more popular. Difficulty is still experienced, however, in convincing patients of the need of submitting to the long treatment and the repeated tests for ensuring cure. The quantity of milk available is said to be inadequate, and its quality leaves much to be desired, though strenuous steps are now being taken to rectify these deficiencies. Dr. Nerurker concludes by stating that the principal causes of the insanitary conditions which maintain the death rate at a high level, even in non-epidemic periods, are the insufficiency of the sewers, the continuance of the basket privy system of conservancy, the density of houses and persons per acre, and the overcrowding in rooms and tenements. The water supply is adequate, the whole being chlorinated throughout the year, and no provision being made for filtration. The medical department is actively engaged in propaganda work and health education.

SCOTLAND

Edinburgh Venereal Diseases Scheme

The annual report for 1936 of the City and Royal Burgh of Edinburgh Venereal Diseases Scheme records the transfer of the wards and clinics at the Royal Infirmary to the new pavilion, which is shared with the department of dermatology. The number of beds available for venereal cases at the Royal Infirmary is now thirty-eight, and a further fifty-two are distributed among other hospitals in the city. In-patients treated during the year show an increase of 20 per cent. over 1935. It is stated that in female cases of severe gonorrhoea or syphilis a spell of intensive treatment in hospital is beneficial, shortening the subsequent period of out-patient attendance, and minimizing the risk of complications, which are especially prone to occur at the menstrual periods. An increase in the number of admissions to the two maternity hospitals indicates a greater interest in ante-natal examination, foreshadowing a diminished incidence of congenital syphilis and ophthalmia neonatorum. The report, stressing the difficulty of combating gonorrhoea, points out that the early symptoms in women are often extremely mild, and that, without microscopic examination, many cases must be overlooked. Also contraceptive practices, which now enjoy a wide vogue, give an impression of security against infection which may not be justified. It is suggested that, from the point of view of prevention, the provision of a hostel for the reception of infected girls is desirable. By this means girls could be removed from the streets during the period of infectivity. With regard to treatment of this disease the administration of acriflavine compounds, in addition to the usual routine irrigations, is producing encouraging results, the tendency to cause jaundice, noticeable in earlier preparations of this type, having so far diminished that no case of jaundice has yet appeared in the course of the investigation which is still proceeding.

Weil's Disease in Aberdeen

The annual report for 1936 of the medical officer of health for the City of Aberdeen includes an account of a special investigation into Weil's disease conducted by Dr. John Smith, regional bacteriologist. The incidence of this disease among fish workers in the city has created a special problem for the health authorities during recent years (*British Medical Journal*, 1934, 2, 1137, and 1936, 2, 1048). During the year under review sixteen cases came to the knowledge of the department, all occurring among employees of the fish trade. Each patient received institutional treatment, and there was one death—a male adult. In the previous year the number of cases was forty. It is stated that Dr. Smith's investigation has been directed towards producing an active immunization of the workers. Experiments on guinea-pigs demonstrated the development of a solid immunity, following the vaccination of the animals with living non-virulent strains or with killed emulsions of virulent strains of *L. icterohaemorrhagiae*. In view of this satisfactory outcome of animal experiments it was decided to test the effect of leptospiral vaccines on selected hospital patients. Mild cases of scarlet fever were chosen, in which the illness had, for all practical purposes, terminated within forty-eight hours of admission of the patient, the majority of whom were children between 8 and 14 years. Three series of patients were vaccinated, each series with a different preparation. Little local disturbance and no general reaction accompanied the vaccinations. In none of them, however, did vaccination stimulate the production of demonstrable immune bodies to the extent that might have been expected. The findings indicate the need for increased dosage to stimulate the further production of immune bodies. It is suggested that their presence, even in small

amounts, should be sufficient to give ample protection, since in the case of patients in the early stage of a leptospiral infection treatment with a dosage of anti-leptospiral serum, insufficient to produce demonstrable foreign immune bodies in blood samples, shows definite clinical evidence of its curative effect. It would therefore appear desirable to vaccinate workers whose daily duties expose them to a possible attack of leptospirosis.

ENGLAND AND WALES

The Hospitals of London

King Edward's Hospital Fund for London has issued a *Statistical Summary* for 1936 (1s., or 1s. 5d. post free, from 10, Old Jewry, E.C.2) of the income, expenditure, work, and costs of 145 London hospitals, from which it appears that there were increases in subscriptions, donations, and receipts on account of services rendered, the total amounting to £3,798,842 ordinary income, as compared with £3,647,311 in 1935. The income from legacies showed a definite fall, however, and the total general fund income amounted to £4,195,925, as compared with £4,196,170 in the previous year. The total general fund expenditure rose from £4,075,115 to £4,259,598, and thus there was a net deficit for the year under review of £63,673, as compared with a net surplus of £121,055 in 1935. This publication comprises an analysis of the general fund income and expenditure of the 145 hospitals, with statistics relating to bed accommodation, patients, and the cost of working, together with particulars of pay-beds and hospitals for infant welfare. It thus enables a financial computation to be made of the position of these hospitals at present, and certain detailed and general deductions can be drawn. Public benevolence towards the sick poor and accident cases still continues at a most meritorious height, but the inevitable expenses show no sign of any reduction, nor is it possible to envisage such relief in the immediate future. There are more in-patients and out-patients; the cost of their treatment has naturally increased slightly, but it would seem that all possible economies are being introduced. The figures for renewals and repairs have somewhat increased, as have also those for provisions, salaries, and domestic activities. These figures do not include capital sums required for rebuilding or for buying new apparatus, and it must be realized that the requirements of this kind will not decrease in the near future but are more likely to extend. The hospital economy committee of the King's Fund is doing its best to assist hospitals in any difficulties experienced in putting into operation the methods of internal control outlined in the appendix to the Revised Uniform System of Hospital Accounts, and the general public may rest assured that everything possible is being done to ensure that all financial assistance is being utilized wisely and well. There are now 18,200 beds available, nearly 200 more than in 1935.

Distribution of Measles Serum

The London Fever Hospital, Liverpool Road, N.1, has asked us to point out that, owing to the great difficulty in obtaining a large amount of convalescent measles serum, its small supply, while always available for the general public, has to be reserved for young children and more especially for weakly and ill children in whom an attack of measles would be dangerous. It is impossible to supply this serum for every contact. The hospital has asked us to point out this to avoid in future the irritation of disappointment of a refusal when general practitioners wish [illegible] older people. The resident medical officer is, however, always glad to hear of cases in which the serum [illegible].

Correspondence

Care of the Vocal Cords in Singers

SIR,—The exigencies of immediate publication prevented me from including in my paper, read in the Section of Oto-rhino-laryngology at Belfast and published in your issue of July 31, an observation which I think is of some importance and which completes the argument I there advanced.

In the paper itself I ventured to make the generalization that there is no such thing as a natural singing voice. I stated that I had never heard of a leading opera singer or even a chorus singer at Covent Garden who had not been taught how to sing, and that singing is an acquired art; wherefore it follows that with increased knowledge and experience and more care of the vocal cords the best voices have yet to be heard.

An interesting comment on this view is afforded by an experience I have had of original singing of the same kind as must have been heard perhaps thousands of years ago. From 1923 onwards I have had the good fortune to visit Central and East Africa on many occasions, traversing unknown paths in the Sudan, Abyssinia, Uganda, Kenya, and Tanganyika. In the remote parts of these areas, especially on festival days, I came across occasional groups of primitive natives singing either casually among themselves or deliberately to encourage dancing, which would go on for hours on end. The singing was accompanied by tom-toms, the drums originally used for conveying messages or warnings from tribe to tribe. But what singing it was! None of the women or children sang, but only the men, and in their singing voices there was not a semblance of resonance, harmony, or musical quality, the notes being usually limited to three or four. In all these regions this rough production and quality was about the same. Among these people there was no balance or synchronization between the singing and the speaking voice. Yet the vocal cords of the primitive African are the same to all appearance as those of the cultivated European. If singing is a natural endowment the apparatus is available.

This observation appears to me to bear out the point I made in my paper that the vocal cords are not constructed by Nature for singing purposes.

If there is any fallacy in this comparison I should be happy to have it pointed out. Let me apologize to you, Sir, for taking up your space with this postscript.—I am, etc.,

London, W.1, July 31. MILSOM REES.

Visual Standards for Aviators

SIR,—In view of the publicity which is now being given to the visual standards set for civil aviators, and the criticisms which are being offered in this connexion, may I reply to the letter by Mr. Myles Bickerton printed in the *Journal* of July 17?

First of all, nearly everything in this connexion was discussed in my lecture before the Ophthalmological Congress in Oxford this summer, and will appear in due course in the *Transactions*. For our present purpose it should be realized that we are dealing only with civil aviators. Now civil aviators have this peculiarity—namely, that they are not a local or even a national affair, but become international property so far as their medical (in-

cluding visual) standards are concerned. It is evident that my friend Mr. Bickerton, with whom I shared both the dissecting room at Cambridge and parts of the River Cam during our mutual studies at the University, has never faced the International Convention of Air Navigation in Paris with the purpose in hand of fighting for reasonable visual standards in the interests of our civil pilots and of flying in general. Had he done so he would appreciate that it is no mean task.

The last two visits to Paris have been devoted by me in endeavouring to obtain certain reductions in visual acuity for B licence (passenger-carrying) pilots, and also some alteration in the strict ruling for colour vision. The A licence pilot has in these discussions followed the same pathway, his visual acuity, however, being based on correction by glasses to the necessary vision.

The feeling which tends to creep into aviation circles that the medical authorities are working overtime to make things difficult is unfortunate, as exactly the reverse is the case. The consultant staff at the Central Medical Establishment are constantly reviewing the standards in order to fit that which is practical and common sense into the general scheme of progress. If this particular work in Paris had not been undertaken in the interest of civil pilots, several of our best men would now be on the ground.

The whole point at issue with regard to *one-eyed* pilots is that of their danger, not to themselves if it amuses them to take risks in the air, but to others who, being visually normal, may become the victims of their fellow club-member's blindness. As I said in my Oxford lecture, the problem of the bad eye is not one of *visual acuity* but of *visual field*, as there is no question whatsoever that a pilot with a completely blind eye, either through extreme injury or actual excision, is a source of very potential danger to others in the air. If, as Mr. Bickerton remarks, there are 700,000 people handicapped in this fashion in varying degrees, it is the more important that we proceed with reason with regard to the slackening of standards. I wonder what the attitude of the passenger of the air would be towards his future travel if it was shown at a coroner's inquest that a one-eyed A licence pilot, through his visual handicap, had turned into an air liner in flight and killed the occupants?

I know of no regulations passed regarding pre-1919 pilots being permitted to fly on an A licence having sustained loss of one eye. All present standards fall within I.C.A.N. regulations, a large volume of some 120 pages, and certain local British adjustments for our own benefit, set down in Air Navigation Directions 1936 (A.N.D. 13), obtainable from H.M. Stationery Office.—I am, etc.,

P. C. LIVINGSTON, F.R.C.S.Ed., D.O.M.S.,
Wing Commander; Consultant in Ophthalmology, Royal Air Force.

Central Medical Establishment,
Royal Air Force,
July 27.

Pulp-space Infection

SIR,—I read with interest Mr. James Hardman's admirable review of pulp-space infection in the *Journal* of July 24 (p. 156). I would especially commend his classification and the influence which this has on the actual incision.

In 1930 I was instrumental in inaugurating a "septic hand clinic" at the Liverpool Royal Infirmary, as I felt that the importance of these conditions could not be overestimated. Although agreeing in the main with Mr. Hardman's views, I dislike the transfixion operation which he advocates. Kanavel points out that the blood supply of the diaphysis of the terminal phalanx is derived largely from the vessels in the closed fibrous compartments of the pulp, and that thrombosis of these vessels causes bony necrosis. A transfixion operation such as Mr. Hardman practises must divide many such vessels running to the periosteum, and thus predisposes to necrosis of bone. A lateral incision down to, and draining, the pus pocket need not necessarily transfix the finger, and will not injure more vessels than is absolutely necessary.

Again, it is not desirable to use rubber drainage material in the majority of these cases, as the pressure of the rubber drain sometimes tends to cause sloughing of the fibro-fatty "filling" of the pulp. The finger is already swollen, and a linear incision immediately becomes an elliptical gap providing adequate drainage without any further interference. Sloughing of part of the fibro-fatty pad can cause as serious sequelae as necrosis of the diaphysis, since the loss of the pulp leaves the digit with a tender extremity not suited for pressure-bearing, and permits the nail to become deformed, curving forwards towards the ventral aspect. Lastly, a straight wooden splint maintains the finger in an uncomfortable posture; a small curved metal gutter splint allowing slight flexion at all three joints is preferable.—I am, etc.,

Liverpool, July 26. J. COSBIE ROSS.

Elongation and Dilatation of the Colon

SIR,—Professor J. R. Learmonth's interesting and instructive contribution to your issue of July 24 (p. 154), while well calculated to clear the ground and to emphasize the fundamental distinction between megacolon proper and the peculiar redundancy of the colon known as *dolichocolon*, appears to shrink from some of the conclusions which can be drawn from a consideration of this somewhat difficult subject. Without agreeing with Mr. Slesinger (*Lancet*, 1926, 2, 274) that dolichosigmoid forms in itself a sufficient indication for colectomy, we must maintain the standpoint we took in your columns four years ago (1933, 2, 1), that dolichosigmoid, though not in itself a "surgical lesion," is, from its nature, peculiarly liable to give rise to surgical complications. The occurrence of mesosigmoiditis, or of adhesions following pelvic inflammation, etc., will tend to fix and approximate the ends of the elongated loop, and if the elongation is sufficient all the factors required for the production of a volvulus are present.

The study of the clinical and radiological features in such cases led us to the view that a certain class of patient, not by any means of extreme rarity, does actually suffer from symptoms due to recurrent attacks of sigmoid volvulus. They present exactly the features long ago described by Edgren and others as premonitory of sigmoid volvulus, as noted in the previous histories of patients admitted for acute intestinal obstruction from this cause—namely, chronic constipation, pain on defaecation, attacks of local distension, attacks of colicky pain followed by watery or sometimes blood-stained diarrhoea, the diarrhoea being caused by a transudation from the bowel consequent on venous occlusion from torsion. Such cases are still too often classed casually as "colitis" without any genuine attempt being made to arrive at a correct diagnosis.

Their radiological examination, which must include a combined air-and-barium filling of the colon, will show: (i) an elongated sigmoid, the essential predisposing factor; (ii) fixation and approximation of two points at either end of the loop; (iii) occasionally an actual torsion of the

folds of the colonic mucous membrane will be seen, generally above the lesion.

The combination of (i) and (ii) may give rise to recurrent attacks of volvulus, which, in our experience, is a not infrequent cause of chronic invalidism; as to its prognosis we may quote Pauchet: "*Le volvulus n'est jamais un accident; c'est une échéance.*"

It thus appears advisable to distinguish at least three types of dolichosigmoid: simple dolichosigmoid, which is not an indication for surgery; dolichosigmoid complicated by megasigmoid, for which sympathectomy may be indicated; and dolichosigmoid complicated by mesosigmoiditis or other local cause, producing a recurrent volvulus, for which the treatment is surgical, and in our experience excision of the loop, followed by end-to-end junction, has given the best results.—We are, etc.,

D. Ligat.
T. D. Overend.

St Leonards-on-Sea, July 26

When to Operate in Appendicitis

Sir,—Mr McNeill Love has given us a most clear and concise account of the "expectant" method of treatment of acute appendicitis; he estimates the proportion of cases in which the method has to be abandoned, and the method may be said to have failed, at 10 per cent. I would like to point out another weakness in this method, which concerns those patients in whom the treatment has been successful in the first place but who then fail to return according to plan to have the appendix removed at a later date. Such cases are not uncommon, and the following is an example.

A male, aged 20 years, was admitted to St. James's Hospital on April 27, 1936, with acute appendicitis of sixty hours' duration. An "indefinite swelling" was palpable. Expectant treatment was instituted with the happy result that resolution occurred; the patient left hospital without operation, and was free from symptoms on May 13, 1936. The most emphatic instruction was given that he was to return in three months' time for appendicectomy (as is the routine in such cases). This instruction he ignored, and his next appearance was on September 5, 1936, when he was brought to hospital again, this time with a well-formed appendix abscess. Simple drainage was performed, and the patient left hospital after the wound had healed again with emphatic instruction about returning for appendicectomy—which he again ignored. On July 19, 1937, the patient returned to hospital with a third appendical attack; a definite mass was palpable on admission, but appendicectomy was performed on July 24, 1937—not without some little difficulty. The patient is now convalescent.

"All's well that ends well" will be the obvious comment for the disciples of Ochsner and Sherren to make; but it seems reasonable to assume that the patient would have been subjected to less risk had an immediate appendicectomy been performed on his first admission to hospital in April, 1936—apart from the fact that he has been an invalid on and off for fifteen months owing to appendix trouble.

Of course if it were possible to kidnap these defaulting patients on the expiry of the appropriate three months the monotonous sequence of events in the present case would have been cut short. But there is, unfortunately for the success of the expectant treatment, no provision for such a contingency. The responsibility for these cases is not discharged until appendicectomy has been performed, and when accidents occur owing to the patient's neglect to return the surgeon is indirectly responsible in that he might have prevented any such possibility by an [illegible] operation in the first place.

[illegible] expectant treatment is contemplated, it would [illegible] necessary (among other things) to estimate [illegible] of a person the patient is, and whether he is likely to carry out instructions when he leaves hospital. Otherwise the end-result may be that this method of treatment fails, albeit the immediate surgical "expectations" are completely realized.—I am, etc.,

St. James's Hospital, S.W.12, Aug. 1. R. S. Lawson, M.S.

Chronic Monocytic Leukaemia

Sir,—I have read with interest Dr. J. D. Hay's letter (July 24, p. 184) concerning the size of the spleen in monocytic leukaemia, a point discussed in my article in the *Journal* of July 3 (p. 1). In Osgood's article (*Arch. int. Med.*, 1937, **59**, 931) an analysis is made of all cases reported as monocytic leukaemia, the strength of the evidence for the diagnosis being very variable in different cases. Osgood states that in 84 per cent. of 117 cases the spleen was reported as being enlarged, either "palpable, enlarged to percussion, or of definitely increased weight at necropsy," and the average weight in the few cases in adults in which it was recorded was 473 grammes, which would generally mean palpable enlargement. In view of this it would perhaps be better to say that most cases of monocytic leukaemia are acute, and that there is usually only moderate splenic enlargement. Dr. Hay doubts the wisdom of gauging the chronicity of a case of this description by the degree of splenomegaly. I fully agree that a case may be of some duration without having much splenic enlargement, but the converse, I think, does not hold. As I stated in my article, I consider extreme splenomegaly (in my case the spleen weighed 1,531 grammes) to imply chronicity, and chronicity in monocytic leukaemia is a very rare feature.—I am, etc.,

Manchester, July 26. G. Stewart Smith.

Hereditary Sebaceous Cysts

Sir,—I think that cases of hereditary sebaceous cysts of the scalp, such as that described in the *Journal* of July 24 (p. 185), are the least uncommon variety of sebocystomatosis (Pringle's steatocystoma multiplex), well illustrated by the condition in two brothers demonstrated by Dr. A. Schlüter and myself at the Dermatological Section of the Royal Society of Medicine (autumn, 1936). In those two brothers most of the surface of the body was affected. The cysts were chiefly small, but there were also larger ones. Those on the fingers were conspicuous; those on the scrotum were typical; and one in the groin was large enough at first sight to resemble an inguinal hernia.

In the *Urologic and Cutaneous Review* for July, 1937, I drew attention to another (? not hereditary) type of sebocystomatosis. The patient was a young woman who had minute cutaneous cysts almost limited to the axillae. Microscopical examination (Dr. W. Freudenthal) showed them to arise from the hair follicles. Their position suggested that they might have been derived from apocrine glands, but on careful examination no dilated apocrine tubercles were found.—I am, etc.,

London, W., July 28. F. Parkes Weber.

Ionization for Hay Fever

Sir,—In the *Journal* of July 31 (p. 245) Mr. C. A. Hutchinson criticizes me on three points, but to all of them I still adhere. (1) Fibrinous exudate after ionization I have seen, and damage to cilia is the point of the American criticism. But the mucosa recovers. And therefore (2) metaplasia does not usually occur, or at least persist. Only once have I seen a case of hay fever with meta-

plasia and that was one of pronounced atrophic rhinitis. This man has had only one attack, promptly relieved by one ionization. It is conceivable that a mucosa that has had repeated cauterization may show metaplasia, but for my statement that the nose is normal between attacks my critic will find confirmation on page 723 of Coca, Walzer, and Thommen's authoritative book, and they have had vastly more experience of hay fever than I. There is no metaplasia in the nose of the doctor whose case I quoted. On the contrary, he has a slight tendency to polyp formation, and polypi are common material for the demonstration of cilia to students. (3) Mr. Hutchinson says that for paroxysmal rhinorrhoea ionization is palliative, "very rarely curative." Why, then, object to my expression "mostly futile"? I tried to indicate a better, because more permanent, way.—I am, etc.,

JAMES ADAM.

Glasgow, July 31.

Agranulocytosis and Para-aminobenzenesulphonamide

SIR,—I have had the opportunity of observing a case similar to the one reported by Dr. C. I. Young (*Journal*, July 17, p. 105).

The patient was a young man aged 20, who was suffering from acute rheumatism with pains in the joints and pyrexia. He could not remember having had any previous attacks. The heart showed clinical signs of old endocardial lesions—aortic regurgitation and mitral stenosis—and there was evidence of a superimposed infective endocarditis—enlarged spleen, clubbed fingers, and pallor. The blood culture was negative and the leucocyte count was 6,100 per c.mm.

The patient was given 90 grains of sodium salicylate daily, but the pyrexia never subsided for any length of time. Sixteen days after admission the leucocyte count was 8,200 per c.mm. Twenty-three days after admission he was put on para-aminobenzenesulphonamide (proseptasine, May and Baker), 3 grammes daily. His condition did not improve, and the drug was discontinued after eighteen days. Again the blood culture was negative. Two days later the patient had only 600 leucocytes per c.mm. (45 per cent. haemoglobin, 2,800,000 erythrocytes per c.mm.), and greyish-white spots appeared in the pharynx. On the same evening 300 leucocytes per c.mm. were present. He received a blood transfusion and pentnucleotide. The next day he died. The leucocyte count before death was 1,000 per c.mm., all the cells being lymphocytes.

Although there is no proof that agranulocytosis was due to para-aminobenzenesulphonamide, this case and Dr. Young's case suggest the advisability of a daily leucocyte count in cases in which this drug is given over long periods. (See also *J. Amer. med. Ass.*, 1927, **89**, 1377.)—I am, etc.,

ALFRED MODEL.

Leeds, July 23.

Prominal in Epilepsy

SIR,—I was interested in the articles published in the *Journal* of July 10 by Dr. Guy Millman and Dr. C. J. Henderson on their experiences of the use of prominal in substitution for luminal in the treatment of epilepsy, as I have been using luminal since 1913, and latterly prominal, also in such cases. Both these drugs are superior to the bromides in many cases in reducing the frequency of the fits. They have the further advantage over the bromides in not producing the same dulling effect on the mentality of the individual. But both luminal and prominal are of foreign manufacture and are very expensive preparations.

I wish therefore to draw attention to "phenobarbitone soluble," the "home-made" product, which is obtainable at one-fifth the price and produces equally good results, as I mentioned in my report on the Devon Mental Hospital for 1934. New preparations for the treatment of epilepsy spring up in the market like mushrooms, but we have yet to find *a cure* for this disease.—I am, etc.,

RICHARD EAGER.

Countess Weir, Nr. Exeter, Aug. 2.

More Light—Better Sight?

SIR,—That maximum visual acuity does not occur beyond a certain intensity of light has for long been understood by physicists. On July 16, 1857, the late John Tyndall, F.R.S., spent an interesting day on the Mer de Glace making observations on the appearances presented by "dirt-bands." In his book, *The Glaciers of the Alps*, inscribed to Michael Faraday in 1860 he wrote:

"The illumination of the glacier has great influence upon the appearance of the bands; they are best seen in a subdued light, and I think for the following reasons: The dirt-bands are seen simply because they send less light to the eye than the clearer portions of the glacier which lie between them; two surfaces, differently illuminated, are presented to the eye, and it is found that this difference is more observable when the light is that of evening than when it is that of noon."

"It is only within certain limits that the eye is able to perceive differences of intensity in different lights; beyond a certain intensity, if I may use the expression, light ceases to be light and becomes a pain. The naked eye can detect no difference in brightness between the electric light and the limelight, although when we come to strict measurement the former may possess many times the intensity of the latter. It follows from this that we might reduce the ordinary electric light to a fraction of its intensity without any perceptible change of brightness to the naked eye which looks at it. But if we reduce the limelight in the same proportion the effect would be very different. This light lies much nearer to the limit at which the eye can appreciate differences of brightness, and its reduction might bring it quite within this limit and make is sensibly dimmer than before. Hence we see that when two sources of intense light are presented to the eye, by reducing both the lights in the same proportion the *difference* between them may become more perceptible.

"Now the dirt-bands and the spaces between them resemble in some measure the two lights above mentioned. By the full glare of noon both are so strongly illuminated that the difference which the eye perceives is very small; as the evening advances the light of both is lowered in the same proportion, but the differential effect upon the eye is thereby augmented, and the bands are consequently more clearly seen."

—I am, etc.,

ANDREW FERGUS.

Hindhead, July 25.

Ocular Headache

SIR,—I am grateful to Mr. L. G. Scoular for raising several critical points in his letter (July 24, p. 186), and for the opportunity to reply to them in extension of my paper on ocular headache.

To me there must exist some doubt concerning the undemonstrable hypothesis that astigmatism and hypermetropia give rise to headaches solely by imposing "some kind of strain on the ciliary muscle." I would like to draw attention to the rarity of complaints of headache of ocular origin in individuals with only one useful eye, even though this may be a hypermetropic one. The squinter who has suspended the use of one eye has solved his muscle-balance problem in his own way, and though

he often needs to make a considerable effort of the ciliary muscle for unaided close work does not seem to be so liable to headaches from this cause. The discomfort occasioned by astigmatic errors "against the rule" or at an oblique angle is due, as I believe, to our adoption of letter forms suited to the physiological majority. Sufferers from discomfort of this nature are likely to associate their headaches with ocular effort and to take direct measures to secure attention to their eyes. They will tell their doctor that their eyes are troubling them and merely seek his help as an intermediary to obtaining specialist advice. The standard of ventilation of public places of entertainment is higher than it was, but cinema eye ache continues to be more conjunctival than visual, often by atmospheric aggravation of an antecedent conjunctival congestion which may or may not be referable to refractive error. The conditions cited by your correspondent having obvious pointers to the source of the trouble are unlikely to mislead, and are omitted with intent from my paper in order to confine it to acceptable if condensed limits. It is in cases of migraine and in obscurer types of headache generally that the practitioner may find assistance from a simple estimate of the near point eye muscle balance in bringing to order the vague history given by a patient, possibly regarded on other excellent grounds as neurasthenic.

Mr. Scoular, having, like myself, served a brief apprenticeship in general practice, appreciates that the practitioner has neither the time, the inclination, nor the proficiency for accurate retinoscopy (in diminishing order of insuperability). My paper was written and compressed to an economic minimum of these three—and of equipment expense that any practitioner can achieve, and that will be of practical use to him in a life already fully occupied in the wider aspects of medicine, of which headache in general, and ocular headache in particular, are relatively minor details. If in attempting to cover the matter briefly my remarks appear unduly dogmatic I ask Mr. Scoular to ascribe it to the exigencies of space rather than a failure to keep an open mind.—I am, etc.,

Hull, July 29 STENHOUSE STEWART.

Commerce Without Conscience

SIR,—The article on this subject in the issue of July 24 (p. 178) is the best thing I have read for many a day, and is not without a fair amount of subtle humour which makes it all the more enjoyable. Could it not find its way into the public press? For, while the *Journal* can be seen in many public libraries and elsewhere, it is not widely read by the patent medicine consumers.—I am, etc.,

Leven, Fife, July 26. R. B. G.

The British standard specification for centrifuge tubes and sedimentation vessels for the determination of visible dirt in milk, No. 736, which has just been published by the British Standards Institution, has been prepared at the request of and in co-operation with the Dirt in Milk Subcommittee of the Analytical Methods Committee formed by the Society of Public Analysts and other Analytical Chemists. The centrifuge tubes are primarily designed for the determination of visible dirt in milk by the method developed by the above subcommittee and described in its report (*Analyst*, 1937, **62**, 287). It is anticipated, however, that the tubes may be found of use in other applications besides the one for which they are primarily designed. Copies of this British Standard (No. 736–1937) may be obtained from the Publications Department, British Standards Institution, 24, Victoria Street, S.W.1, price 2s. post free.

Obituary

PROFESSOR F. DE LAPERSONNE

As briefly announced in our last issue France's Grand Old Man in ophthalmology, Professor Félix de Lapersonne, has passed away after a prolonged illness which, though it robbed him of the use of his legs, failed to cloud his indomitable spirit. His personal charm and air of old-fashioned distinction marked him out wherever medical men met, and he carried his many honours with an easy graciousness. Born in 1853 in Toulouse, he was an intern in a Toulouse and later in a Paris hospital. He served under Le Dentu, Péan, and Panas, being the latter's first assistant in the ophthalmological service of the Hôtel-Dieu. In 1886 he moved to Lille, where he became professor of clinical ophthalmology in 1890 and doyen from 1893 to 1901. On the retirement of Professor Panas he succeeded in 1901 to the chair of clinical ophthalmology at the Hôtel-Dieu, and here he remained till 1924. In 1918 he was elected a member of the Academy of Medicine, and he became its president in 1931. As the first President of the International Association for the Prevention of Blindness he proved both an ornamental figurehead and an inspiring organizer in spite of his advanced years. A list of the many ophthalmological subjects on which he published original studies is given in *La Presse Médicale* for July 14. He was, by the way, a very active member of the scientific board of this weekly publication.

By the death of Dr. ALEXANDER MORTON on July 18 at the age of 82 Glasgow loses its oldest and one of its ablest dermatologists. At the University there he took his M.A. degree in 1876, graduated in medicine in 1880, and proceeded to the M.D. in 1885. Although for many years he was a general practitioner he had paid special attention to skin diseases and studied in Dublin and Vienna. He became a member of the Dermatological Society, lecturer on dermatology at St. Mungo's College, and physician for diseases of the skin in Glasgow Royal Infirmary. Dr. Morton had been a member of the British Medical Association for thirty-three years, and when the Association met at Edinburgh in 1898 he acted as a vice-president of the Section of Dermatology. As a consultant he developed an extensive practice, and no doubt he owed much of his success in the treatment of "skins" where others failed to his long experience in general practice, for those practitioners who sent him their patients realized that he was no mere "oleaginous physician," but treated the skin from the inside as well as from the outside. During his later career he was much handicapped by steadily increasing otosclerotic deafness. Nevertheless he was able to handle successfully difficult cases almost up to the time of his death. If genius is the capacity for taking pains Alex. Morton had it, and could make his patients attend to those minutiae essential to success in dermatology. He will be missed by patients and colleagues alike.

J. A.

Dr. CHARLES HENRY BURTON THOMPSON died in Suva, Fiji, on June 22, as the result of a spinal injury incurred by falling from a horse on June 22. He was then in his 57th year. A student of the Middlesex Hospital, he obtained the diplomas M.R.C.S., L.R.C.P. in 1907; he became D.P.H.St. Andrews in 1924, and D.T.M.Liverp. in 1925. His earlier appointments included those of house-surgeon to the Oxford Eye Hospital and ophthalmic and aural surgeon to No. 19 General Military Hospital. He was a member of the British Medical Association. After qualification he practised in India from 1911 to 1914, before which he had been assistant medical officer of

health to the Somerset County Council, and filled appointments at the Moorfields Eye Hospital, the Royal Westminster Ophthalmic Hospital, the Golden Square Ear and Throat Hospital, the Queen Square Hospital, and the West End Hospital for Nervous Diseases. Just before going out to Fiji in 1925 he had been resident medical officer at the Highfield Sanatorium, Liverpool. At Suva he was medical officer of health and school medical officer, and an official member of the Suva Town Board; he was very popular and highly esteemed in Fiji. As port medical officer there he made numerous friends. His funeral on June 23 was attended by a large number of his friends and colleagues, students from the Central Medical School acting as pall-bearers. After the service at the graveside three volleys were fired by a detachment of the Fiji Defence Corps, and the Last Post was sounded. The cathedral service was taken by the Bishop of Polynesia. Dr. Thompson leaves a widow, and a daughter aged 16.

We regret to announce the death on July 21 at Llandrindod Wells, Radnorshire, of Dr. JOHN MURRAY, O.B.E. He was born in Glasgow on February 5, 1871, the son of Alexander Murray, and from Hutcheson's Grammar School went to study medicine at Anderson's College and the University of Glasgow, graduating M.B., C.M. in 1894. Dr. Murray practised for many years at Llandrindod Wells, and was appointed medical officer to the hospital in 1905; he was also medical officer to the Post Office and certifying factory surgeon. During the war he served as major, R.A.M.C.(T.F.). He joined the British Medical Association in 1907, and had been president of the Shropshire and Mid-Wales Branch.

Medico-Legal

SEPTICAEMIA OR AGRANULOCYTOSIS?

The Manchester city coroner recently heard an inquest on a woman of 59 who died in the Manchester Royal Infirmary. Her husband said that she had taken "yeast-vite" tablets at intervals since 1931. She had been in fairly good health until June 3, but on June 5 she became very ill and the doctor sent her to hospital. She took two tablets after each of her meals on June 3 and 4. She had scratched her finger by some unknown means shortly before her illness. Her general practitioner stated that on June 5 she had a high temperature. He had incised a red swelling on her finger, but she had shown no signs of septicaemia. He had sent her to hospital next day with a diagnosis of some form of blood poisoning. She died on June 14. The city analyst said he had recovered no poison from any organ. The tablets had contained 12.1 per cent. by weight of amidopyrine and 6 per cent. of phenacetin. He thought that death was accelerated by the drug, and said that on certain types of persons it would have a very specific and harmful effect.

The coroner adjourned the inquest for the manufacturers to be represented, and at the adjourned hearing the manager of the local co-operative stores said he had sold "yeast-vite" to the deceased since 1931; he had never received a communication from the manufacturers about the substitution of a new formula or any restrictions on its sale. Counsel for the stores said that a notice calling in all "yeast-vite" stocks was contained in the weekly price list sent out on May 8, 1936. Counsel for the manufacturers, Mr. G. D. Roberts, K.C., said that the tablets had been sold at the rate of 80,000,000 a year for many years and that they had been suspected in only one case, that of a young woman who had died in 1935. Her death had been found due to septic teeth. Since that time, however, amidopyrine had been left out of the tablets. Dr. D. L. Griffiths expressed the opinion that death was due to agranulocytosis caused by amidopyrine and not to septicaemia. There were no micro-organisms in the blood. Sir William Willcox said he had no doubt that death was due to septicaemia caused by the wound in the finger. It was inconceivable that the doses taken on June 3 and 4 could have caused the dramatically acute symptoms. On the question of an idiosyncrasy, he remarked that she had been taking amidopyrine for years, and if she had had an idiosyncrasy it would have manifested itself some time before.

The jury returned an open verdict that death was due to a toxic condition without sufficient evidence to show the type or cause.

Medical Notes in Parliament

In the House of Lords, on July 30, the Royal Assent was given to the Finance Act, the Factories Act, the Local Government Superannuation (Scotland) Act, the Agriculture Act, the Matrimonial Causes Act, the Cinematograph Films Act, the Coal Mines (Employment of Boys) Act, the Local Government Superannuation Act, the Milk (Amendment) Act, the Royal Samaritan Hospital for Women Glasgow Order Confirmation Act, the Ministry of Health Provisional Order Confirmation (South-East Essex Joint Hospital District) Act, and the Liverpool United Hospital Act.

Bills introduced this session but now dropped include the Divorce (Scotland) Bill, Infanticide Bill, Local Authorities (Hours of Employment in Connexion with Hospitals and Institutions) Bill, Protection of Animals Bill, Registration and Regulation of Osteopaths Bill, and the Seafish (Dyeing and Colouring Prohibition) Bill. The Prohibition of Vivisection on Dogs (Scotland) Bill is listed as withdrawn.

Both Houses now stand adjourned till October 21.

Health of Scotland

An estimate was discussed in the House of Commons on July 22 for completing the sum required towards the salaries and expenses of the Department of Health for Scotland, including the grant-in-aid of the Highlands and Islands Medical Service and other services. The debate which followed was chiefly concerned with housing in Scotland. Dr. ELLIOT said the Scottish building industry showed a great output, but it was working under big strain. There was a shortage of men and, to a smaller extent, a shortage of certain materials. The Department was endeavouring to stimulate greater activity following the publication of a Report on Rural Housing, and a circular had been issued to all county councils recommending a more adequate inspection of rural houses and special surveys of the houses for farm servants and crofters.

Mr. FOOT spoke of overcrowding in Dundee, where, he said, there was no prospect of houses under the 1935 Act being available for two or three years for the relief of overcrowding.

Mr. LEONARD asked what was being done to urge local authorities to supply domestic helps, especially in view of the fact that the duties of midwives in the future would differ from what they had been in the past, when midwives were able to give domestic help in addition to their other duties. He also asked the Department to attend to the question of maternity homes. Under the Maternity Homes Act it was possible for a maternity home to have only one qualified person, and that person might be the superintendent herself. The total number of maternity homes registered with Scottish local authorities in February, 1937, was 146, and the nurses employed in the homes numbered 747. The nurses who had neither the Central Midwives Board qualification nor were registered in the general part of the registry of nurses numbered 107. If in some maternity homes there was not a proper proportion of qualified nurses he hoped the Department would take the matter up. Mr. WESTWOOD said the estimates only provided £36,000, as against £70,000 last year, for water supplies in rural areas. This was insufficient. In regard to building, twenty authorities had stopped building because of rising costs.

HIGHLANDS AND ISLANDS MEDICAL SERVICE

Mr MALCOLM MACMILLAN drew attention to the difficulties in the Highlands and Islands Medical Service of those who had to travel long distances to isolated cases in out-of-the-way places. Lack of transport added to the difficulty of serving people as they should be served. Nothing had been done since Dr Elliot took office to improve the lot of doctors and nurses in the Western Isles. Often the patient had to be carried from the far end of Harris to Stornaway to get to the only hospitals with proper equipment and accommodation. The telephone service required extension and improvement and the water supply should be improved, for many places in the Islands depended on shallow supplies which were used by cattle as well as by human beings. There was no communal sanitation in the Western Isles outside Stornaway and perhaps two other towns. Serious consideration should be given to the development of the air service for ambulance purposes. Housing was bad in the Western Isles; there were hundreds of ill-ventilated, dark, and insanitary houses. Fortunately new houses were being built with Government assistance, but the lack of water was felt in these houses also, and they had no internal water supply.

Mr BUCHANAN said last year 60,000 applications were made in Glasgow for houses, and this year nearly 8,000 more people wanted houses. On June 30, 1936, there were under construction in Glasgow for overcrowding and slum clearance, and for ordinary purposes without State assistance, a total of 2,687 houses. This year at the same period the total was 2,839. There was practically no change. There was an increase in those authorized but not begun. In his own division 1,700 houses were unfit for human habitation.

Mr. GUY doubted whether the total given by Dr. Elliot of 17,000 new houses to be built by Scottish local authorities in 1937 would be completed. In Edinburgh at the present rate of progress thirty to thirty-five years would be required to eliminate the condemned and overcrowded houses.

Replying to the debate Mr. WEDDERBURN said the present rate of slum clearance was satisfactory by comparison with the rate for any year previous to 1933, but unsatisfactory because it did not suffice to remove slums, let alone overcrowding, within a reasonable period of time. In 1933 it was hoped that both in England and in Scotland slums would be removed by the end of 1938. Since then they had removed 43,000 slum houses in Scotland, but the Department of Health estimated that there was probably another 15,000 houses to be removed. Whether this would be done in another five years depended entirely upon additional provisions which the Department had been able to make for increasing the supply of labour.

The proposal to reduce the estimate was defeated.

Milk Regulations

In the House of Commons, on July 23, Mr. W. S. MORRISON moved that the amendments of the Milk Marketing Scheme, 1933, be approved. He said of 44,000 producers who had voted on the draft amendments 87 per cent. were in favour. A public inquiry had subsequently been held and the amendments, with certain modifications, had been assented to by the Milk Board. Amendment 2 gave power to the Board to regulate the manner in which milk might be graded by, or on behalf of, traders and producers. Producers of tuberculin-tested milk were brought into the scheme for the first time to secure that this milk should be marketed through the national organization under conditions which would encourage the continued production of this valuable article.

Mr. A. V. ALEXANDER said regard ought to be had to the difficulties which had arisen in connexion with the cancellation of contracts where producers had been found guilty by the Courts of adulterating milk. He knew of a case in which [illegible] were found guilty of wilful adulteration, but the Board was compelled to continue to accept supplies from [illegible]. Adulterated or unsatisfactory milk should be [illegible] not fit for sale, and a producer who had [illegible] of producing unsatisfactory milk should be prevented from selling milk until he provided evidence that it was suitable. He doubted whether producers of graded and tested milk were being called upon to make a sufficient contribution in comparison with other producers who had to contribute to the pool. For some time bodies like the Food Council and the Consumers Committee had made references, not always favourable, to the possibility of having milk delivered without the process services of pasteurization and bottling to be sold at differential prices. The argument was that the price of milk could be reduced if the consumer paid only for the type of service rendered. Behind that lay the more important consideration of public health. In the epidemic last year at Bournemouth over fifty deaths and over 500 cases of typhoid fever were traced to the supply of milk from one producer who sold milk raw. At this moment two municipal corporations, Poole and Glasgow, had Bills before the House with a clause in each taking compulsory pasteurization powers. The Ministry of Health had deferred the matter and was looking into it. The Government had also asked all local authorities who supplied milk to school children that as far as possible they should supply pasteurized milk. Under the amendments the producer-retailer who did not pasteurize would be placed in a favourable position in relation to the majority of the trade who had laid down expensive plants for the pasteurization and bottling of milk in the interests of public health.

Mr. MACQUISTEN said the milk which Mr. Alexander called "raw" was fresh milk and the only milk worth drinking. Pasteurized milk was half-boiled milk. The motive behind the proposal for compulsory pasteurization was to get all the milk into the hands of monopolies. If calves were fed on pasteurized milk they died, and rats who were fed on it failed to reproduce their species. Surely it was better that people should boil their milk when they needed it rather than it should be boiled forty-eight hours before in a factory. If this milk were sold as "half-boiled milk" it would not be so popular. The one bright spot in the Minister's scheme was that it was going to reduce the levy on the tuberculin-tested producer to ½d. per gallon. That would go some distance towards purifying the herd. Why did the doctors not clamour for tuberculin-tested milk instead of bringing all this pressure to bear in favour of pasteurized milk? The result of regulation in Scotland had been that the retail price of milk was now 2s. 4d. a gallon. It was no use talking about nutrition so long as that was the Milk Board's price and so long as a man who sold his milk cheaper was treated like a felon.

Mr. W. S. MORRISON, replying to Mr. Alexander's question on contracts with producers convicted of adulteration, said the crime of adulteration carried its own penalty, and he did not think that cases were sufficiently numerous to warrant any objection to the amendment as proposed. There was often a great deal of doubt whether milk had been adulterated or not. Many producer-retailers did their best, with success, to supply decent milk, and if producers as a whole were willing to carry out their obligations the House could rest assured. The Department was not departing from its endeavour to get the quality of milk supplied by producer-retailers up to a higher standard. There was ample inducement for progress in supplying clean and wholesome milk.

The House then approved the amendments.

Safety in Mines

The House of Commons in Committee on July 26 considered the vote for the salaries and expenses of the Mines Department of the Board of Trade. Captain CROOKSHANK said that questions affecting the health and safety of the 780,000 men employed in the mining industry—silicosis, nystagmus, and so on—must be the constant preoccupation of anyone who held the office of Secretary to the Mines Department. Although in certain directions they could note a reduction, they could not be merely complacent in the matter; they must regard it merely as a starting-point for further efforts in the future. The Royal Commission on Safety and Health had been labouring very strenuously during the last year, and was still sitting. In

1936 790 persons were killed in the collieries, one or two of whom, for some unusual reason, were women. This was the lowest figure on record for a full year's working, and would have been more impressive but for the major disaster last August at Wharncliffe Woodmoor. On the basis of 1,000,000 tons of coal raised the number of killed came out at 3.36, which was the lowest figure on record, or 0.39 per 100,000 man-shifts worked, which was better than anything since 1924. Unfortunately there had been an increase in the number of persons killed in the first six months of this year.

One aspect, however, was a most bitter disappointment to all. In spite of all that had been done by boys' classes, training grounds, safety officers, and propaganda to decrease the accident rate for boys, this had moved upwards in the last year. The number of boys employed had also moved up. Something was still very wrong somewhere. A great deal more supervision was required, and older and more experienced men as well as officials could do much by saying the right word in due season. In the last six months 29,000 boys were employed: twenty-nine were killed, and the number of three-days disablement cases was 5,942. For the previous six months the figures were 30,000 boys employed, twenty-four killed, and 5,487 disabled for three days. The safety classes movement had gone on with great strength, and had been satisfactorily started in every coalfield except South Wales, but recently intensive efforts had been made by local authorities, coal owners, officials, and workers to co-operate and improve the position. The movement deserved far wider support in South Wales, if for no other reason than that the accident rate for boys there was higher than the general average for the country. They had had great support for these safety classes from the Safety First Association, which published a very striking poster that had had a wide distribution.

There had been a tremendous increase in the use of protective equipment. Last year the number of hard hats supplied rose by no fewer than 150,000, and in the Swansea area there was a very noticeable increase in the use of hard hats from 700 at the beginning of the year to 4,425 at the end. There were many pits where the hard hat was universally used, and the effects were now beginning to be seen. The number of injuries which lasted for more than a fortnight were proportionately less than they used to be, and the number of injuries lasting less than a fortnight had gone up. Head injuries, which in 1935 were 6.27 per 100,000 man-shifts worked, dropped last year to 5.56. The difference in the proportion of those injured for less than two weeks was 49 per cent. for 1936, compared with 45 per cent. in 1931, and those injured for over two weeks was 51 per cent., compared with 55 per cent. for 1931.

INCREASE IN THE INJURED

He had presented a report on the inquiry into the explosion at the Wharncliffe Woodmoor Colliery last August, which raised an important problem in connexion with stone dust. In this case it was clear that although stone dusting was, generally speaking, carried on in accordance with the regulations, it was ineffective in the roadways in preventing the spread and development of the initial fire-damp explosion. He had been considering new regulations dealing with stone dust, and these had now been circulated for preliminary consultation with the usual bodies concerned. It had not yet been possible to publish the reports of the district inspectors for 1936, and he was sorry to say that the figures of those injured altogether, 136,000, showed an increase over the previous year of 2,000. That showed, in addition to what he had said about boys, that they could not afford to relax any of the precautions that could be taken. Unfortunately, the inspectors' reports showed many cases where accidents might perhaps have been avoided. He appealed to the makers of all machinery which might be used, either underground or on the surface, to do everything possible to provide the most efficient guards.

As to silicosis he had nothing particular to say at the moment. The Medical Research Council had recently requested the Industrial Pulmonary Diseases Committee to start a comprehensive investigation into silicosis and allied pulmonary diseases in South Wales. That was a step to which he had given his strongest support. The Miners' Welfare Fund had assisted financially, and the South Wales Miners' Federation had promised to give all the co-operation that it could. The inspectors would continue to give all the assistance in their power, and Captain Hay, one of the inspectors, had been specially detailed for this work, and spent the whole of his time co-operating with mine and quarry managements in trying to devise the best means of prevention. Under the Factories Bill quarries and pit banks of metalliferous mines would be left out of the Factories Act administration, and would come under the Mines and Quarries Acts administration. For that purpose they would be transferred from the Home Office to the Mines Department. Consequently it was necessary to draw up new regulations to deal with this problem, and that was now being done.

Mr. J. GRIFFITHS: The Minister said that the Medical Research Council by arrangement with the industry was to investigate the purely medical side of the problem. It will spend most of its time investigating the question of what are the precise diseases from which the men who are disabled are suffering, and which are declared to be other than silicosis. Will anything be done at the same time or afterwards to investigate thoroughly the problem of how the disease can be prevented?

Captain CROOKSHANK: Generally speaking, one needs to know what a thing is before one can prevent it. Captain Hay, as I have said, spends the whole of his time trying to devise methods of prevention.

Mr. PALING moved to reduce the vote. He said that in view of the boasted progress in the science of mining it seemed incredible that the accident rate in mines could not be reduced. The figures meant that on an average every man working underground met with an accident once every five years. The number killed approximated to nearly 1,000 each year.

Captain CROOKSHANK, replying to points raised in the debate, said that with regard to accidents to boys in 1936 in the group 14 to 16 there were twenty-nine killed and 5,932 injured, and in the group 16 and under 18 there were twenty-six killed and 8,247 injured.

The motion to reduce the vote was negatived, and the vote agreed to.

Research into Animal Diseases

During the debate in the House of Lords on July 26 on the report stage of the Agriculture Bill Lord ADDISON asked for an assurance from the Government that financial assistance for research into animal diseases was practicable under the Bill. He said it was a vital part of the attack on disease that the Council for Scientific Research into Animal Diseases should be very generously assisted.

The EARL OF FEVERSHAM said that Clause 20 of the Bill enabled the department to make grants to the Agricultural Research Council. The money provided by the clause was merely limited by the vote of Parliament.

The Bill was read a third time on July 28.

Milk Pasteurization

In the House of Commons, on July 27, Mr. MACQUISTEN asked leave to introduce a Bill to prohibit the use of the designation "pasteurized" in connexion with the sale of milk, to enforce the use of truly descriptive designations in connexion with the sale of any milk heated above a certain temperature, and to amend the Milk and Dairies (Amendment) Act, 1922. He said he hoped that the Bill would be accepted and that no longer would the misleading word "pasteurized" be used in regard to milk. He did not believe that pasteurization made milk any more sanitary, because it was much more liable to infection afterwards. Pasteurized milk was only half-boiled milk cooled down, and it would be better for everybody if it was accurately described. Great pressure was being put on the Ministry of Health to make pasteurization compulsory. The great monopolies hoped that

it that were done all the milk would be driven through their hands. Fresh milk was the only milk worth drinking. He did not believe in an inquiry by the Ministry of Health. If half-boiled milk was good, why did the medical profession not spread among their patients the idea of boiling their own milk instead of leaving it to go through the dairies, where it was liable to pick up infection after it was pasteurized? Possibly there were some medical officers of health who were in favour of compulsory pasteurization. He always looked upon these officers as men who did not want to go out into the open and fight for a living, but wanted jobs with a pension attached. The Minister of Health was the person who had to defend sippers dipped in creosote for so many years. He did not want these monstrosities forced upon the community for the benefit of commercial interests. There should be truthful description of milk so that the public would know what they were getting.

MR. LEONARD opposed the Bill on the grounds of public health. He said he was surprised that Mr. Macquisten should make this attack upon the health machinery of the country, which had been built up with so much trouble to bring it to its present standard. Pasteurization was well understood; it was not boiled milk. Some people thought that it led to dirty milk, or induced farmers to be lax in their methods of milk production, but that was not the case.

Leave to bring in the Bill was refused.

On July 27 SIR THOMAS MOORE asked the Secretary of State for Scotland whether his attention had been called to the report issued by the milk production department of the West of Scotland Agricultural College with regard to the deleterious effect of pasteurizing milk, and what proportion of the milk used in connexion with the milk-in-schools scheme under his Department was pasteurized and fresh respectively. Dr. ELLIOT said he had seen the report in question, which related to an experiment into the relative value of raw and pasteurized milk in calf feeding. The results of any single experiment had to be taken in conjunction with a great number of other experiments on this subject, which had been and were being made. Fifty-three per cent. of the milk used in connexion with the milk-in-schools scheme in Scotland was pasteurized and 47 per cent. untreated. A large proportion of the milk in both categories was tuberculin tested.

Silicosis

On July 27 MR. GORDON MACDONALD asked the Home Secretary the number of patients alleged to be suffering from silicosis that had been submitted to the medical board during each of the last five years and the number certified as suffering from the disease.

MR. LLOYD circulated the following statement:

Examinations by the Medical Board in Pursuance of Applications for Death and Disablement Certificates from Silicosis or Silicosis Accompanied by Tuberculosis

Year	Disablement		Death	
	Workers examined	Certified to be wholly or partially disabled by the disease	Applications dealt with	Certified to be caused by the disease
1933	1,091	449	281	197
1934	827	435	225	174
1935	630	410	201	147
1936	549	429	191	143
1937	504	342	173	133
Total	3,721	2,155	1,071	794

Air Raid Precautions

[illegible] a report stage of the salary of [illegible] Secretary of State for War, Mr. HORE-BELISHA, Secretary of State for the Home Department, and Sir THOMAS INSKIP, Minister for the Co-ordination of Defence in the House of Commons on July 27 Sir THOMAS INSKIP said that a great deal of work had been done concerning air raid precautions, and the fact that discussions had taken place with local authorities about the financial responsibility indicated that the plans had reached an advanced stage. The whole country had been surveyed and divided into zones, in some of which preparations must be on a more elaborate scale than others, according to proximity to any menace. When the discussions on finance had ended in a proper settlement these plans could be effectively executed. He saw no reason why they should not now begin at once to carry out the plans so carefully and elaborately made. Sir Thomas subsequently announced that the Calcium Carbide Committee had been asked to present a report not later than the middle of September, so that the Government should be able to prepare any requisite legislation.

Factories Bill

The Lords' amendments to the Factories Bill were considered by the House of Commons on July 27. On the new clause proposing to allow the periods of employment for persons under 16 to end later than 6 p.m. but not later than 7 provided the total hours worked did not exceed 44 in any week, and where on at least one weekday in addition to Saturday these persons were not employed either before or after the midday meal, Mr. GEOFFREY LLOYD proposed that the Commons agree with the Lords in this amendment. Subsequent speeches, however, were critical, and when the debate was resumed on July 28 he announced that the Home Office did not propose to press the new clause, which was, in consequence, negatived. The other amendments made by the House of Lords were accepted and the Bill was returned to the Upper House.

Cost of Living and Nutrition

On the Consolidated Fund (Appropriation) Bill in the House of Commons on July 28 Mr. DAVID GRENFELL opened a debate on the cost of living. He said that the cost of living scales vaguely reflected the conditions of life of a very large number of people. He understood there was in progress a survey of the effectiveness of this instrument for gauging the purchasing power and social conditions of the community. The scale had moved upwards in the last four years at a more or less steady pace.

Mr. GRAHAM-WHITE said 4,500,000 people in this country spent on an average only 4s. a week on food; another five millions spent only 6s.; another nine million spent only 8s., although the Nutrition Committee of the British Medical Association had fixed 7s. a week as the minimum required for a reasonable physical existence. Havoc would be wrought in a multitude of homes if the cost of living continued to rise. The basis of the cost of living index should have the complete confidence of the people, because in the heavy industries the remuneration of at least one million people fluctuated with it, and in important sections of the Civil Service salaries varied with variations in the cost of living. Was the House and the country to have any information on this important matter before about this time next year? A significant fact with regard to the cost of living was that there had been no seasonal decline this year, and he presumed there would be a much steeper rise before Christmas than occurred last year. If the rise went on it might well lead to an increase in the mortality rates, which varied according to the standards of living and nutrition.

VARYING STANDARDS OF LIVING

Sir ARNOLD WILSON said that when the nation was short of food in 1914–18 there was an actual diminution of mortality, and at present in Germany, which unquestionably had no surplus of food, the expectation of life at any age above 5 was four years in excess of the corresponding expectation in this country. In the United Kingdom wage rates were slightly higher than in 1929 and the cost of living was slightly lower, but as a result of abnormally low prices of food during the past five years persons on the lowest wage levels had become accustomed to spending rather less on food and rather more

on the minor comforts of life. The quantity of meat eaten was going up rather rapidly in spite of higher prices, as also that of butter, margarine, cheese, milk, beef, and bread, although 10 per cent. less bread was consumed than was the case ten years ago. There was an increase in the total consumption of food, and there were on the average fewer dependents in a family than in 1929. There was more money to spend in any given family than there was in 1929. The true standard of living in this country might not have risen, but the standard had become more costly. There had been a 20 per cent. increase in the last six years in the consumption of tobacco, cosmetics, and sweetmeats, and in visits to cinemas, and also an increase of something like 10 per cent. in the consumption of liquor. The total sum expended on such luxuries was something like £250 million to £300 million a year. Perhaps it was due to the pressure of advertisements that the nation consumed less of some essential commodities like fish and bread, and vastly more of quasi-luxury commodities like tobacco. The cost of living ought to be divided into separate categories, comprising first, elementary needs; secondly, conventional needs; and thirdly, luxuries which could be dispensed with. Now that prices were rising it should be considered whether the cost of dying ought not to be included in the cost of living. Burial costs were roughly £10 million per annum in this country, and of this seven to eight millions fell on the wage-earning classes.

Mr. OLIVER STANLEY said it was difficult to reply to the many points raised in the debate. The index for the cost of food was above what it was twelve months ago, and still more above the year 1933, but below what it was in July, 1930, and considerably below what it was in 1929. In so far as the rise in the cost of food-stuffs was a world trend produced by greater demand was it in fact something which in general was injurious to the health of this country? A rise in commodity prices which took people off unemployment assistance and gave them increased purchasing power more than made up the difference in prices to them. If the health of the country depended on food prices falling as low as possible, then the years 1930 to 1933 ought to have been years in which this country had much greater prosperity than was in fact the case.

Miss LLOYD GEORGE said Sir John Orr had reported that practically half the population of this country suffered from undernourishment. He said that a year ago, since when the cost of food had risen, and the serious factor was that it was increased in price. The price of food had risen by 10 per cent. with the exception of milk, which had the nutritive foods,

UNEMPLOYMENT ASSISTANCE

Mr. JAMES GRIFFITHS said that the scales of allowances fixed in reference to the needs of applicants under the Unemployment Assistance Board were decided in July, 1936, as meeting the needs of unemployed persons at that date, when the cost of living index figure was 46. What should the scales be in July, 1937, when the figure was 55? The Government should see that the allowances were increased proportionately.

Mr. SHINWELL said 214,000 old age pensioners were in receipt of public assistance, and persons in receipt of outdoor relief in 1936 in England and Wales numbered 1,200,000. What kind of life must it be for these persons. The British Medical Association laid down a minimum of 5s. 7¾d. as the lowest possible standard on which a person could live for a week.

Colonel COLVILLE said an inquiry into working-class expenditure would be undertaken in the autumn with a view to revision of the cost of living index. Full consideration would be given to all the points which had been raised in the debate. The inquiries would be conducted with the assistance of local committees set up for the purpose and households from which information was desired would be visited personally. There would be no time lost, but a reliable picture on which to base future calculations could not be secured if they hurried too much. Meanwhile the present cost of living index figure gave a good picture on which to proceed. To link old age and widows' pensions with the cost of living would be very unfortunate for the pensioners. If that had been done in 1919 the pension to-day would be 6s. 9d. The Appropriation Bill was then read a second time.

Health in Barbados

A statement made on behalf of the Colonial Office on July 28, by Sir LAMBERT WARD announced that a Committee on Problems of Nutrition, appointed by the Governor of Barbados, had recently reported, and as a result of its recommendations proposals for the establishment of infant welfare clinics and crèches in all the parishes, on lines similar to those at present existing in two of them, were under discussion. Arrangements for the establishment of a system of daily distribution of milk and biscuits to elementary school children were also under consideration by the Barbados Education Board. An important source of ill-health in the Colony was overcrowding and bad housing, and an attempt had been made to remedy this by the establishment of a housing board, which was empowered to order the alteration, repair, or demolition of houses which were injurious to health or unfit for human habitation, and to acquire land and build suitable houses.

Tuberculosis in Scotland

On July 29 Dr. ELLIOT circulated a table relating to the incidence and fatality of tuberculosis in Scotland as follows:

Year	Incidence. Number of Notifications			Fatality. Number of Deaths			Death Rates per 100,000 Population		
	P.	N.P.	All Forms	P.	N.P.	All Forms	P.	N.P.	All Forms
1934 ..	4,985	3,066	8,051	2,793	911	3,704	57	18	75
1935 ..	4,939	2,951	7,890	2,811	836	3,647	57	17	74

P.=Pulmonary. N.P.=Non-pulmonary.

Post Office Administration

In the House of Commons on July 29, on the third reading of the Appropriation Bill, Mr. VIANT opened a debate on Post Office administration. He condemned the amount of overtime worked in the Post Office, and said it was general throughout all departments. The health statistics spoke for themselves, as showing the number of days lost through sickness aggravated by overtime.

Major TRYON said while he agreed on the importance of reducing overtime, there did not seem to be a good foundation for suggesting that overtime had led to sickness in the Post Office, in view of the fact that sickness had not been so low for a long time. In 1936 the rate of sickness among men was the lowest since 1914, and that of sickness among women was the lowest since 1906.

Sir WALTER WOMERSLEY said in reviewing because of health reasons the question of bringing the temporary postmen on to the permanent staff the Department was bound to take into consideration the conditions of the service. No service in this country was more generous in treatment of men who were ill. Full wages were paid, medical attention was given, and only when it was beyond doubt that the person was unlikely to render useful service to the Department did the question of superannuating him out of the service arise. When a person went into temporary service it was pointed out to him that there was no obligation on the part of the Postmaster-General to find him permanent employment. After further discussion the Appropriation Bill was read a third time.

Liverpool United Hospital Bill

The Committee on Private Bills, which examined the Liverpool United Hospital Bill, reported that the object of the Bill was to amalgamate the Liverpool Royal Infirmary, the David Lewis Northern Hospital at Liverpool, the Royal Southern Hospital at Liverpool, and the Liverpool Stanley Hospital in one corporation to be called the Liverpool United Hospital, and to make provision with respect to the property and funds of the said hospitals and the management of the amalgamated

hospitals. A report from the Attorney-General relative to the Bill was referred to the committee, who found that except as regards Clause 40 of the Scheme scheduled in the Bill, the recommendations contained in the report had been complied with by amendments made in the Bill during its passage through the House of Lords. With regard to Clause 40, the committee found that the Bill had been amended in the House of Lords to provide (*a*) that an investment committee should be appointed consisting of the chairman, the deputy chairman, the treasurer, and not more than three members of the general committee of the hospital; (*b*) that the investments of trust monies of the hospital should be subject to the approval of the investment committee; (*c*) that a list of the investments should be available for inspection by any governor; and (*d*) that the powers of investment to be authorized by the Act should not apply to funds on the investment of which there were any existing restrictions.

Working Hours of Nurses.—Sir FRANK SANDERSON asked on July 22 whether the Minister of Health would consider introducing legislation making it compulsory upon all hospital authorities to introduce an eight-hour day for their nursing staff, in view of the great strain imposed upon them by the existing eleven-hour day, and the consequent detrimental effect upon the health of the patients. Sir KINGSLEY WOOD answered that the question of the working hours of hospital nurses was one of a number of matters affecting the nursing profession which engaged his attention. The associations representing local authorities were in communication with the General Nursing Council regarding certain measures for meeting the situation.

Anti-dysentery Treatment.—Mr. GROVES asked on July 23 if Bristol public assistance committee had purchased a large quantity of anti-dysentery bilivaccine in order to make an extensive trial of it on patients at the Stapleton institution; by what method the vaccine was administered; and what need there was for it at that particular institution. Sir KINGSLEY WOOD replied that he was in communication with Bristol City Council on this matter.

Civilian Practitioners and Emergency Service in Military Hospitals.—On July 27 Mr. HORE-BELISHA, replying to a question, said that lists of medical practitioners willing to serve in a civil capacity at military hospitals in the United Kingdom in place of the Royal Army Medical Corps until such time as they were relieved by the R.A.M.C. officers were kept in each Command.

Slums in Glasgow.—On July 27 Dr. ELLIOT, replying to Mr. Stephen, said that 622 houses in the Camlachie Parliamentary Division of Glasgow were being dealt with under the Housing Acts as unfit for human habitation, or were on the corporation's list awaiting such action. The numbers of unfit houses closed or demolished during 1935, 1936, and the first half of 1937 were 167, 153, and 28 respectively. The latest available information with regard to the number of overcrowded houses in the division was obtained as a result of the overcrowding survey at the end of 1935, when the number was 5,660. The number of houses built by the Glasgow Corporation in the division in each of the six years 1931 to 1936 was: 1931, 294; 1932, 108; 1933 and 1934, none; 1935, 54; and 1936, none. The corporation had thirty houses in course of erection in the division, and proposals under consideration for the building of approximately 770.

Regional Supply Depot for Respirators.—Mr. LLOYD, replying to Mr. Kirby on July 27, said that a large regional supply depot for gas respirators had been established in Liverpool. It came into occupation on July 19, and was now ready for the reception of the respirators.

Nutrition and Unemployment Assistance.—On July 27 Mr. [illegible] Smith asked the Minister of Health whether the committee of inquiry into the question of nutrition had had under consideration the scales of unemployment assistance; and, if so, whether they were considered adequate, especially in relation to the cost of foodstuffs. Mr. BURGESS [illegible] Advisory Committee on Nutrition was dealing with the general question of the diet of the people, and dietary surveys were at present being undertaken in certain areas which dealt with working-class families, and which might include persons in receipt of public assistance.

Funds and Expenditure of Approved Societies.—On July 27 Sir KINGSLEY WOOD informed Mr. Gibson that 849 approved societies were carrying on business in the United Kingdom under the National Health Insurance Acts on December 31, 1936. Information was not available as to the total amount of insurance funds held by approved societies at the end of their last financial year, but the report by the Government Actuary on the Fourth Valuation of Approved Societies (Cmd. 5496) showed that the total of such funds at that valuation amounted to £164,363,000. The total amount expended by approved societies on sickness and disablement benefit in 1936 was approximately £17,612,000.

Provision of Meals at Instruction Centres.—On July 27 Mr. ERNEST BROWN informed Mr. G. Hall that he had decided to adopt the recommendations of the National Advisory Council for Juvenile Employment for England and Wales on the provision of meals for juveniles in attendance at juvenile instruction centres. He proposed to take the necessary steps to give legislative effect to them at the earliest opportunity.

Medical Examination in Drunkenness Charges.—Sir JOHN MELLOR, on July 29, asked the Home Secretary to take steps to secure that any person detained in custody upon the charge of driving a motor vehicle while under the influence of drink should, as soon as the police surgeon was sent for, be informed of his right to request the attendance of a doctor of his own selection. Sir SAMUEL HOARE said the practice of the Metropolitan Police was to inform any person in custody on this charge that it was open to him to have a doctor of his own choice called on the understanding that he would pay the doctor's fee. The general practice in other police forces was similar. He would look into the matter further if there was any reason to think that this procedure was not followed. He could not say whether the privilege of requesting a doctor of his own choice extended to prisoners other than motoring offenders.

Milk Consumption in Special Areas.—In an answer to Miss Irene Ward, on July 29, Mr. W. S. MORRISON said schemes for the supply of milk at cheap rates to expectant and nursing mothers and children under 5 years were now in operation in the Rhondda Valley, Jarrow, and Walker-on-Tyne. On July 17 in the Rhondda the numbers participating were 860 expectant mothers, 519 nursing mothers, and 5,389 children under 5. In Jarrow these figures were respectively 135, 83, and 1,281; in Walker-on-Tyne they were 107, 214, and 1,401. The average daily consumption under the scheme during July in Rhondda was 4,923 pints, in Jarrow 1,095 pints, and in Walker-on-Tyne 1,289 pints. The milk was sold at 1s. 4d. a gallon compared with the normal price of 2s. or 2s. 4d. a gallon.

Mental Health in the Fitness Campaign.—Sir FRANCIS FREMANTLE, on July 29, asked whether the Minister of Health, having regard to the vital importance of mental health to the community and the growing public interest and need of enlightenment in the subject, would have it included in the health campaign propaganda to be carried out in the autumn under the auspices of the Government. Sir KINGSLEY WOOD replied that opportunities would certainly be taken in the course of the campaign to call attention to the importance of mental as well as bodily health.

Operation of Midwives Act in Wales.—Mr. JAMES GRIFFITHS asked, on July 29, whether the responsible authorities in Wales had submitted satisfactory proposals for the provision of an adequate service under the provisions of the Midwives Act, 1936. Sir KINGSLEY answered that all the local supervising authorities in Wales except one had submitted proposals which were generally satisfactory, although in some instances points of detail were still under consideration. The authority which had not yet submitted proposals

that could be regarded as satisfactory was considering the submission of revised proposals. He was satisfied an adequate service could be established in Wales within the financial and other provisions of the Act.

Hearing Aids: Advertisements in Stamp Books.—On July 29 Sir ARNOLD WILSON asked the Postmaster-General whether, in view of the recent discussions of the British Medical Association at Belfast and of the recommendations of the Select Committee on Patent Medicines in 1914, he would give further consideration to the expediency of excluding advertisements of aids to hearing from postage-stamp books sold by his Department, and what, if any, financial loss would be occasioned thereby. Sir WALTER WOMERSLEY, in reply, said Major Tryon had referred to reports of the recent discussions of the British Medical Association on this matter and could find in them no reason for modifying the present policy of the Post Office, which was confirmed a few months ago after careful consideration. The financial loss from the exclusion of advertisements of aids to hearing would be upwards of £3,000 a year.

Tuberculosis in Wales.—Sir KINGSLEY WOOD told Mr. James Griffiths, on July 29, that he was not in a position to make a statement on the result of his consultations with the Welsh National Memorial Association in reference to the steps to be taken to deal more effectively with the problem of tuberculosis in Wales. He was at all times in close touch with the work of the association, and a survey of the services it provided was being carried out by a medical officer of the Welsh Board of Health. He awaited the report on that survey, and hoped to meet representatives of the association and of the local authorities when he visited South Wales in the autumn.

Silicosis and Asbestosis.—Sir SAMUEL HOARE told Mr. Kelly, on July 30, that cases of silicosis and asbestosis were not reportable to the Home Office as and when they occurred, but according to the annual return from the Medical Board for 1936 they certified 551 cases in that year, and in addition certified 198 deaths to have been caused by one or other of these diseases.

Machine Drilling and Silicosis.—Mr. D. GRENFELL asked the Secretary for Mines whether he would authorize the collection of the fullest possible information at mines where more than three cases of silicosis had been certified, showing the names and addresses of men who, in the last twenty years, had been engaged in boring with the use of machines either in hard headings or in ripping, with the type of machines used, and the yardage of hard headings driven. Captain CROOKSHANK replied that he was in full sympathy with the general object in view, but he did not think an investigation on the lines proposed could prove sufficient or satisfactory. There were cases of silicosis among coal miners who had never used machine drills. Moreover, the nature and extent of disability in a particular case could not be reliably determined without medical examination.

Notes in Brief

In the past twelve months 74,631 houses were inspected in Liverpool, 3,380 being found to be unfit for human habitation and a further 29,800 not to be in all respects reasonably fit.

During 1936 there were ten fatal and 2,776 non-fatal accidents to boys under 18 in South Wales and Monmouthshire. The corresponding figure for fatal accidents in the first half of 1937 was five.

Of 100,000 road accidents involving personal injury between April and September, 1936, the reporting authorities attributed to drivers, cyclists, or pedestrians under the influence of drink or drugs as the sole or main cause 14 fatal and 538 non-fatal accidents and, as a contributory cause, 10 fatal and 61 non-fatal accidents.

Some action with regard to immunization against diphtheria is taken by the councils of approximately seventy-four county boroughs, 117 non-county boroughs, twenty-eight metropolitan boroughs, and five counties in England and Wales.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on August 1 the following medical degrees were conferred:

B.M.—M. H. Hughes, A. R. Norton, T. B. Snell, D. I. Crowther, R. H. S. Thompson, W. B. Young.

UNIVERSITY OF CAMBRIDGE

D. J. Bauer of Trinity College has been elected to the Michael Foster Studentship in Physiology.

The following candidates have been approved at the examinations indicated.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Part I:* E. H. Allen, Margaret McL. M. Morrison, J. K. Muir, V. G. Vohra. *Part II:* A. P. Booth, Jean Bouchard, J. A. Brocklebank, C. J. C. Cooke, M. W. Dahab, G. G. Doel, A. M. Evans, W. Irwin, M. Lederman, C. T. MacCarthy, J. R. M. Martin, V. Prakash, H. Pringle, R. R. Rishi, D. C. Virmani, V. G. Vohra, J. W. Winchester.

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

M.D.—*Branch I (Medicine)*: E. G. H. Cowen, Constance E. Field, G. W. Hayward, A. G. Hounslow, *A. Nelson-Jones. *Branch II (Pathology)*: J. L. Hamilton-Paterson, *H. A. Magnus. *Branch IV (Midwifery and Diseases of Women)*: V. H. J. Davies, R. Evans, *J. Howkins, M.S., S. P. Mason.

* University Medal.

The Senate on July 21 awarded the Ph.D. in Medical and Vital Statistics (non-clinical) to William John Martin (London School of Hygiene and Tropical Medicine); and the Ph.D. in Medicine (non-clinical) to John Douglas Robertson (Middlesex Hospital Medical School).

UNIVERSITY OF MANCHESTER

The following appointments have been made:

Assistant Lecturer in Anatomy: E. L. Patterson, M.B., Ch.B. *Assistant Lecturer in Applied Physiology*: Margaret I. Williams, M.B., Ch.B. *Demonstrators in Anatomy*: D. D. Cranna, M.B., Ch.B., D. A. Richmond, M.B., Ch.B., and F. W. Smith, M.B., Ch.B. *Clinical Lecturer in Infectious Diseases*: John Yule, M.D., D.P.H.

The Pilkington Fellowship in Cancer Research has been awarded to Mrs. Edith Paterson, M.B., Ch.B.Ed.

QUEEN'S UNIVERSITY, BELFAST

At a meeting of the Senate held on July 27, Mr. J. R. Wheeler, F.R.C.S., was appointed Lecturer in Ophthalmology, and Mr. C. H. G. Macafee, F.R.C.S., and Mr. H. I. McClure, F.R.C.S., Lecturers in Midwifery and Gynaecology.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary meeting of the Council of the Royal College of Surgeons of England was held on July 29, with the President, Sir Cuthbert Wallace, Bt., in the chair.

The Hallett Prize was presented to Alexander James Innes. Dr. W. d'A. Maycock was reappointed a Leverhulme Scholar from August 11, 1937, to September 30, 1938, and Mr. T. Stewart Heslop was reappointed a Leverhulme Scholar for a year from October 1, 1937.

Diplomas

Diplomas of Membership were granted to the following candidates, who have passed the final examination in pathology, medicine, surgery, and midwifery of the Conjoint Examining Board in England:

B. S. S. Acharya, Iris A. Acton, O. B. Alakija, A. L. Alban, H. R. Alban, M. Albert, Mary J. Allardice, E. L. Allen, Sheila M. Anderson, C. E. Aston, E. A. Atkinson, J. C. Babbage, F. B. Bagshaw, J. K. Baker, Mary Baker, T. E. Barlow, V. N. le P. T. Barlow, Mary E. Barnard, Alice J. M. T. Barnes, Laura M. Bates, Eileen M. Bateson, G. K. Beatty, G. H. H. Benham, B. D. Berger, R. D. D. Birdwood, A. B. Birt, H. J. Bliss, L. B. Blomfield, R. Bloom, T. K. Bradford, Katharine M. H. Branson, J. K. Bremer, H. A. Brook, G. R. H. Brown, D. W. Browne, N. J. C. Burnand, Browne, Marjorie G. Bryan, C. T. A. Burgess, W. J. Cohen, J. H. Burniston, H. S. Bury, L. H. Cane, D. W. J. Comyn, Margaret M. T. L. Cohen, A. L. Collins, J. Colover, J. Conway, F. S. Cosh, W. W. Cowen, D. I. Crowther, A. C. Cunliffe,

A. G. Dabbs, A. David, J. B. David, T. I. David, Ll. P. Davies, H. J. Ll. Dickinson, I. Donald, P. W. Edmondson, G. F. Edwards, Phyllis M. Edwards, R. W. Ellis, R. E. Emmott, D. T. H. Evans, E. M. Evans, T. J. Fairbank, Ivy F. Fallon, E. L. Fawssett, W. H. V. D. Ferdinands, A. R. Ford, R. G. D. Forward, Margaret B. Fox, D. L. V. Fraser, Constance M. Fraser, W. K. S. Friedburg, E. Gartside, C. H. George, Rachel Goldenberg, J. Graham, M. P. Graham, W. R. Grant, W. P. Greening, L. Grifliths, T. E. Grifliths, O. Gunnery, H. L. T. J. Hardwick, W. Harris, R. J. Harrison, C. C. Harvey, S. Hazra, S. R. T. Headley, R. P. Hendry, L. H. Henein, F. G. Hibbert, H. G. W. Hoare, A. Homayoun, J. H. S. Hopkins, W. M. L. Horner, T. P. Howkins, E. B. C. Hughes, K. Inamulla, G. S. Irvine, R. C. Jackson, I. Jacobson, S. H. Janikoun, C. T. Jones, T. S. Jones, J. Jordan, G. J. G. King, G. M. Komrower, M. Krone, R. E. Lauder, A. D. Le Vay, C. Levy, Armorel J. Lewis, A. W. Lipmann-Kessel, O. P. Llewellyn, W. A. Lombard, G. Lorriman, P. D. Lynch, L. McAskie, D. H. Mackay, K. R. Mackenzie, R. R. McSwiney, S. A. Maddocks, E. B. Martin, T. K. Maurice, B. N. Mazumdar, P. S. Meyrick, J. R. Miles, A. Miller, C. N. Mills, B. D. Molesworth, E. H. Moore, C. A. Moynihan, Perin K. Mullaferoze, Mary G. Murphy, R. B. Niven, J. H. F. Norbury, J. R. Odell, A. K. Pardhy, W. B. Parker, T. Partington, G. R. Peberdy, G. G. Phipps, T. D. Pilcher, J. C. Prestwich, D. G. Price, G. Quayle, E. P. Quibell, Lilian M. N. Raftery, B. K. Rank, H. M. Rapport, D. C. S. Rendall, S. R. Reynolds, W. N. Riley, C. G. Rob, I. F. Rose, D. Rubin, W. R. Russell, C. P. Sames, H. S. Samuel, S. Samuels, P. J. Schultze, K. B. Scott, C. E. Shafto, R. Shaw, K. M. M. Sheldon, J. Skirrow, A. F. Smith, I. Smith, R. M. Solomon, H. Spencer, J. H. Sproule, R. H. Spurrier, C. M. Squire, Margaret G. S. Stalker, Shelagh M. Streatfeild, A. S. Syed, K. G. Symonds, J. E. Talbot, N. G. G. Talbot, J. H. Taylor, R. W. Thomason, W. G. Tillmann, C. R. Tilly, J. A. F. Tobin, Dorothy C. R. Vethavanam, D. M. Wallace, F. Walt, W. B. Waterfall, J. Watkins-Pitchford, C. Weston, A. B. White, G. D. Wild, P. B. S. Willan, C. B. I. Willey, G. P. Williams, J. M. G. Wilson, W. Windsor, P. N. Witney, G. H. Wooler, Ruth F. Wordsworth.

Diplomas were granted jointly with the Royal College of Physicians of London as follows:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—P. D. Bhargava, A. Carafasingham, S. N. Chelliah, N. Constantoulis, J. De, E. Ll. W. De Silva, S. B. Dhru, A. A. El Moslimani, Annie Foner, M. V. Hargett, E. H. Hudson, P. W. Hutton, X. Khokhongkha, Look-Nyuan Liang, G. D. McLean, E. C. Savona, M. Seraj-ul-Haque, S. B. S. Smith, J. N. Strauss, J. R. de V. Toussaint, J. White.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.—S. M. Ali, T. M. J. Armstrong, H. J. A. Barnard, D. L. Charters, H. R. Cursetji, D. S. Flynn, P. R. Greeves, A. C. L. Houlton, D. Hugo, M. T. Ismail, H. Jamieson, J. R. Kellett, M. A. M. Labib, Josephine M. MacFarlane, T. L. McLarty, V. B. Mankad, I. V. Oza, C. R. Palfreyman, Y. C. Pandit, M. J. Philip, E. V. W. Pockley, P. Ramchander, F. J. Rutter, M. K. Sathe, F. G. Scoles, E. S. Shalom, C. A. Stanley.

DIPLOMA IN MEDICAL RADIOLOGY.—J. A. G. F. Rose, J. E. Swyer.

DIPLOMA IN ANAESTHETICS.—G. E. P. Meldon, H. D. Merrington.

The following hospitals were recognized under the F.R.C.S. regulations: Derbyshire Royal Infirmary, Grimsby and District Hospital, Warneford, Leamington, and South Warwickshire Hospital, Miller Hospital, Greenwich, Woolwich War Memorial Hospital, Northampton General Hospital, Cornelia and East Dorset Hospital.

Sir Holburt Waring was appointed representative of the College on the Newcastle Council of the University of Durham for three years.

The annual meeting of the Association of Surgeons will be held at the College on May 5, 6, and 7, 1938.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a meeting of the Royal College of Physicians of London held on July 29, with the President, Lord Dawson of Penn, in the chair, the following were elected officers for the ensuing year: *Censors*, Gordon M. Holmes, F.R.S., Sir Maurice Cassidy, Albert Ramsbottom, G. E. Beaumont; *Treasurer*, Sidney P. Phillips; *Registrar*, Sir Raymond Crawfurd; *Harveian Librarian*, Arnold Chaplin; *Assistant Registrar*, C. E. Newman.

Dr. S. V. Sewell of Melbourne attended as a distinguished guest.

The Baly Gold Medal was awarded, on the recommendation of the Council, to Professor E. L. Kennaway, F.R.S., for his biochemical investigations which have led to the identification of a group of substances provoking malignant growth of tissues, and having significant relations in structure to certain hormones and vitamins.

Sir Edward Mellanby, F.R.S., was appointed Harveian Orator for 1938.

The Murchison Scholarship was awarded (by the University of Edinburgh) to James Innes, M.B., Ch.B.

The following were appointed representatives of the College: Sir Humphry Rolleston on the Executive Committee of the Imperial Cancer Research Fund; Dr. Edwin Bramwell on the Council of the King's College, Newcastle; Lieut.-Colonel Hugh Stott at the celebration of the fiftieth anniversary of the foundation of the University of Allahabad, November 16, 1937; Professor F. R. Fraser and Colonel A. H. Proctor, Dean of the British Postgraduate Medical School, at the International Congress for Medical Postgraduate Study, Berlin, August 21 to 24; Dr. W. S. C. Copeman at the centenary of the Royal Medical Society of Budapest, October 6 to 8; and Lord Horder, its President, at the International Cremation Congress, London, September 24 to October 2.

Sir Arthur Hurst will deliver the Harveian Oration on October 18 at 4 p.m.

The following candidates, having satisfied the Censors' Board, were admitted Members of the College:

S. Adler, M.B.Leeds, N. S. Alcock, M.B.Ed., D. S. Bateman, B.M., W. Brander, M.D.Aberd., Beatrice A. Butterworth, L.R.C.P., E. M. Buzzard, B.M., J. B. Cable, M.D. New Zealand, L. I. M. Castleden, M.D.Lond., M. C. Chapman, B.M., E. M. Darmady, B.Chir., P. C. Dhanda, M.B.Punjab, D. Diamond, L.R.C.P., P. G. Dowling, M.B.Melb., M. Erfan, M.D.Cairo, Doreen P. Firmin, M.B.Camb., W. H. Gabb, M.B.Camb., A. R. Gilchrist, M.D.Ed., Y. H. Guinena, M.D.Cairo, C. Hardwick, M.B.Camb., F. D. Hart, M.B.Ed., H. T. Howat, M.B.St. Andrews, M. Hynes, M.B.Camb., W. H. Kauntze, M.D.Victoria, W. A. S. Lamborn, L.R.C.P., L. J. M. Laurent, M.B.Lond., D. Levine, L.R.C.P., C. A. Lillicrap, M.B.Lond., L. F. Loutit, B.M., F. McLaggan, M.B.St. Andrews, W. M. Macleod, M.B.Lond., P. [illegible] M.B.Madras, A. Nelson-Jones, M.D.Lond., A. [illegible] B. P. Niyogi, M.B.Calcutta, I. R. Owen, L.R.C.[illegible], M.B.Camb., E. E. Pochin, M.B.Camb., J. D. Ramsay, M.B.Glasg., W. R. Russell, M.D.Ed., J. C. Saldanha, M.B.Lond., O. A. Savage, L.R.C.P., J. E. Sewell, M.D.Melbourne, S. C. Shore, L.R.C.P., T. Simpson, M.B.Leeds, A. J. M. Sinclair, M.D.Melbourne, D. W. G. Smith, M.B.Ed., W. McL. Smithers, M.D.Melbourne, B. Thorne Thorne, M.B.Camb., G. L. B. Thurston, L.R.C.P., W. R. Trotter, B.M., J. W. A. Turner, B.M., R. F. West, M.B.Adelaide, N. Whittaker, L.R.C.P.

Licences and Diplomas

Licences to practise were granted to 206 candidates (including 24 women), whose names are published in the report of the meeting of the Royal College of Surgeons of England in this issue, as are the names of the recipients of the Diplomas in Tropical Medicine and Hygiene (21), Ophthalmic Medicine and Surgery (27), and Medical Radiology (2). Diplomas in Public Health (9), Psychological Medicine (19), and Laryngology and Otology (6) were granted to the successful candidates whose names were published in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of July 17 (p. 143). In the list of the successful candidates for the Diploma in Psychological Medicine the name of J. B. Gillen was misspelt.

The following diplomas were also conferred, jointly with the Royal College of Surgeons of England:

DIPLOMA IN ANAESTHETICS.—M. C. Ganguli, R. E. Pleasance, A. F. Potter, W. B. Primrose, W. Sankey, G. E. P. Meldon, H. D. Merrington, C. D. Banes, R. P. Booth, Elva M. Chivers, R. T. V. Clarke, R. W. Cope, H. Curtis, G. Dru Drury, A. C. Fraser, A. H. Galley, J. L. Hopkins, E. Landau, I. N. Lewis, H. J. V. Morton, A. H. Musgrove, J. A. V. Nicoll, W. Niven, Angela M. S. A. Ofenheim, G. S. W. Organe, F. H. Pratt, A. C. R. Rankin, O. N. Ransford, J. R. Ritchie, Major J. M. Savege, R.A.M.C., Major H. R. Sheppard, R.A.M.C., J. T. Turner, R. C. Walch, Doris E. C. Walker.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At the quarterly meeting of the Council, held in the College House, 58, Queen Anne Street, W., on July 24, Sir Ewen Maclean was re-elected president; Professor R. W. Johnstone and Professor Miles H. Phillips were elected vice-presidents; Mr. Eardley L. Holland, honorary treasurer; Sir Comyns Berkeley, honorary appeal treasurer; Professor W. Fletcher Shaw, honorary secretary; Mr. Frederick Roques, honorary librarian.

The following were admitted to the Fellowship:

Sir Mangaldas V. Mehta, Bombay, Doris C. Gordon, Stratford, New Zealand (*in absentia*), S. Langevin, Montreal (*in absentia*), J. A. Hopkins, Melbourne (*in absentia*).

The following were admitted to the Membership:

A. L. Gilbey, Portsmouth (*in absentia*), J. R. McArthur, Toronto W. L. Maccormac (London), W. J. C. Morris, Ayr, D. C. Racker, Manchester, S. W. Wright, Newcastle-under-Lyme.

The following were elected to the Membership:

M. C. Albuquerque, Bangalore, E. Bailache, Melbourne, S. C. Bose, Calcutta, Marjorie R. E. Boyd, Dublin, F. J. Burke, Liver-

pool, H. Callagher, Melbourne, Isabella D. Cameron, London, H. Canwarden, London, Mrs. D. J. P. Dadabhoy, Bombay, J. P. Dutt, Calcutta, Edith Ghosh, Calcutta, V. B. Gokhale, Belgaum, H. F. P. Grafton, Hamilton, Canada, C. J. K. Hamilton, Liverpool, M. R. W. Hart, Madras, A. F. Hollinrake, Hamilton, Canada, M. Homji, Bombay, J. Howkins, London, J. G. H. Ince, London, Mary John, Inda, J. W. Johnstone, Travancore, Anna P. Martin, L. de Logan, Nagpur, P. Lukose, Korumburra, Australia, R. A. Menezies, Nagpur, E. A. Menon, Waltair, India, D. N. Sarkar, Calcutta, G. A. Simpson, Sernia, Canada, B. H. Singh, Bengal, A. B. Stenhouse, London, R. K. K. Tampan, Edgmore, India, P. Venkatagri, Madras, Margaret Venters, Manchester, R. J. Wotherspoon, Glasgow.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—P. A. Dixon, O. I. Green, C. C. B. Guest, B. A. Hoogewerf, G. Howell, E. S. Reed, O. Rochlin.
MEDICINE.—I. W. Claiman, G. K. Coombes, P. H. Hay-Heddle, K. J. Higham, B. A. Hoogewerf, J. Meynell, J. N. Roberts.
FORENSIC MEDICINE.—I. W. Claiman, P. H. Hay-Heddle, K. J. Higham, B. A. Hoogewerf, J. Meynell, J. N. Roberts.
MIDWIFERY.—M. G. Braham, O. G. Gilmore, L. Gottlieb, K. J. Higham, G. S. Parker, E. F. G. Stewart, C. Webb.

The diploma of the Society has been granted to J. Meynell and J. N. Roberts.

CONJOINT BOARD IN SCOTLAND

The following candidates have been approved at the Final Professional Examination for the Scottish Triple Qualification:

F. E. Adams, E. Adler, G. R. Altmann, J. Anderson, M. Berg, D. Blos, L. A. P. Cantin, W. Carsten, J. P. Chapin, Koh Chiang Chee, L. G. Cruickshank, A. Dzialoszynski, H. Felsen, P. Fleischmann, E. Friedmann, A. M. Gall, D. L. Goldman, D. L. C. Greig, I. M. Greenberger, A. Hirsch, Paula Heimann, W. I. S. Hudleston, F. P. Hudson, A. T. H. A. Kader, A. M. Kallen, Alfaretta F. Keith, J. J. Kristal, R. R. Levine, H. G. Liebmann, K. M. Little, B. Lipschitz, E. W. Lou-Hing, D. M. Macdonald, J. M. Mervis, Cecily C. Mitchell, J. R. Moffat, M. J. Munro, M. K. Naidu, Beryl A. Peters, E. Rachwalsky, H. L. Riner, W. A. Rock, R. W. Ross, M. Rubin, L. Schaffer, I. H. L. Shlefstein, S. Siegel, Charlotte B. Sommer, Betty Spier, F. B. Stephenson, W. H. Suffield, W. S. Thomson, S. P. Vosnides, E. Weltman.

Medical News

The address of the Central Midwives Board for England and Wales is now 23, Great Peter Street, Westminster, S.W.1: telephone number, Victoria 2410.

The Royal Society invites applications for two Foulerton Research Fellowships in Medicine, tenable at any hospital or medical school in the British Isles. Applications must be received by October 16, and candidates must be of British nationality and British parentage. The appointments will be for two years in the first instance, from January 1, 1938, and may be renewed annually up to a total of five years. The stipends will be £600 to £800 per annum, with superanuation benefits.

The lectures and discussions during the third International Medical Week in Switzerland, which will be held at Interlaken from August 29 to September 4, will relate largely to the problems of general biology, affections of the brain and nerves, and the metabolism of carbohydrates. Among the many topics to be considered are recent work in experimentally produced cancer, the results of treatment of intracranial tumours, hereditary factors in tuberculosis and syphilis, insulin therapy, diseases of the skeletal cartilage, and the importance of retinal tension. Excursions are planned to Schynige Platte, Berne, and the Jungfraujoch, while special arrangements are being made for participation in the William Tell festival, which falls due during this congress. The fee for membership is 10 Swiss francs, and further information will be supplied on application to the offices in Basle (27 Klosterberg) of the *Journal Suisse de Médicine*, under whose auspices this medical meeting is being organized.

The second European Congress of Structive (Plastic) Surgery will be held in London at the Royal Society of Medicine on October 6 and 7. Mr. T. Pomfret Kilner has been nominated as president and Drs. Sanvenero-Rosselli (Milan) and Dufourmentel (Paris) as vice-presidents. Sir Harold Gillies will be president of honour and Professor Cardenal of Madrid vice-president of honour. The subjects for discussion are: free skin grafts, nasal contour restoration, and mammaplasty procedures.

All German scientific medical associations and certain foreign associations interested in postgraduate courses for doctors are to be invited to attend a congress for postgraduate medical studies in Berlin from August 19 to 21. It is anticipated that an international committee on postgraduate studies will be appointed on this occasion.

The German Orthopaedic Congress will be held at Rostock from August 27 to 29. Further information can be obtained from the president, Dr. Scheel, Orthopädische Anstalt, Rostock.

We have just received the first number of the first volume of the *Journal of the Malaya Branch of the British Medical Association*, which is edited by Dr. G. V. Allen, in conjunction with Dr. R. B. Hawes, Mr. D. E. C. Mekie, and Dr. J. W. Scharff. This new journal is a workmanlike production, similar in format to the *Transactions of the Royal Society of Tropical Medicine and Hygiene*. We wish it every success. It will be issued quarterly, and can be obtained on application to the Advertising and Publicity Bureau, Ltd., 144, Robinson Road, Singapore, at an annual subscription of 3 dollars. The supplement of this journal includes a report of the Annual Meeting of the Malaya Branch for 1937, and a list of the members of the Branch.

In the *British Journal of Tuberculosis* for July are published all the papers read at the Empire Conference on the Care and After-Care of the Tuberculous held under the chairmanship of the Marquess of Willingdon last May. The transactions of this meeting will not be issued in any other form. Single copies of this issue are on sale at the special price of 4s. 3d., post free.

The Services

DEATHS IN THE SERVICES

Lieut.-Colonel ERNEST GEORGE FFRENCH, R.A.M.C. (ret.), died suddenly on July 25, aged 60. He was born on November 5, 1876, and was educated at St. Bartholomew's Hospital and at Edinburgh University, where he graduated M.B., Ch.B. in 1898, subsequently taking the M.D. in 1906, the F.R.C.S.Ed. in 1909, and the M.R.C.P.Lond. in 1921. After filling the post of house-physician at the Edinburgh Royal Infirmary, he went out to South Africa to serve as a civil surgeon in the South African War in 1900. He took a permanent commission as lieutenant in the R.A.M.C. on May 28, 1901, became major after twelve years' service, and retired, with the rank of lieutenant-colonel, on August 20, 1920. He served in the South African War for two years, 1900–2, taking part in operations in Cape Colony, the Orange River Colony, and the Transvaal, including the action at Renoster Kop, and received the Queen's medal with five clasps. He also served throughout the war of 1914–18, when he was twice mentioned in dispatches. He commanded the Military Hospital at Rochester Row during the war, and served as a specialist in dermatology. Afterwards he acted for six years as chief assistant in the skin department at St. Bartholomew's, was physician in charge of the skin department at the London Temperance Hospital, and practised as a dermatologist and specialist in venereal diseases in Harley Street. He was with C. F. Marshall, author of a work on *Syphilis and Veuereal Disease*. Since 1909 he had been a member of the British Medical Association. When visiting America two years ago he was appointed an associate professor at the New York Polyclinic and Postgraduate School.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.* SECRETARY, *Mediocra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Splitting Finger-nails

Dr. H. STIVEN (Cairo) writes: I have been watching your correspondence columns on the subject of split nails, as I am a sufferer myself. I am a surgeon and use "wet" gloves with lysol, or monsol, or some such tar derivative for my hands after washing up. I have always two or three nails which consistently split, and nothing I try, such as letting them get long, olive oil, vaseline, etc., does any good. That it is not constitutional or due to lack of calcium or vitamins seems to be demonstrated by my toe-nails, which are in good condition. Another complication in my case which may be a factor is that fifteen years ago I was doing my own x-ray examinations, but since then I have completely stopped exposing my hands, as a result of a warning transient erythema, due to operating for a needle in knee-joint under the screen, when, as so often happens, it took longer than expected. I have tried using "dry" gloves at operations with no marked result.

Treatment of Rheumatoid Arthritis

"A. W. S." wishes to know whether there is any special institution for the treatment of a female patient of moderate means with advanced rheumatoid arthritis.

Successive Miscarriages

Dr. A. W. BARCLAY WIGGINS (Sheffield) writes in reply to Dr. O. Sydenham (*Journal*, July 31, p. 252): I had a similar case of successive miscarriages in a patient of the anaemic, red-haired type; no pelvic abnormality was detected and her Wassermann reaction and the husband's were negative. She came to me early in the last pregnancy, and in spite of the negative Wassermann I gave her a full course of N.A.B. She was delivered of a healthy female child at the thirty-ninth week. The child is now 2 years old and appears normal. I may add that the husband had suffered from malaria while on military service in India.

Dr. A. W. PURDIL (Acton, W.3) writes: Perhaps Dr. O. Sydenham would be interested in Professor James Young's article "Habitual Abortion and Stillbirth Syndrome," which appeared in the *Journal* of May 8, 1937.

Agranulocytosis and Rheumatism

Dr. D. H. COLLINS, in reply to Mr. L. A. Riddell (*Journal*, July 24, p. 197), writes: A severe and chronic polymorphonuclear leucopenia (neutropenia) is a rare but not unknown concomitant of rheumatoid arthritis. It is usually associated with enlargement of the liver and spleen, and this combination of findings has received the name of "Felty's syndrome," but the associated arthritis appears to differ in no respect from rheumatoid arthritis. The neutropenia, although sometimes as low as 100 polymorphonuclear leucocytes per c.mm., does not appear to influence the prognosis and seems to occur irrespective of the treatment given, though of course amidopyrine and the sulphonamide preparations should be considered as possible aetiological factors. The neutropenia is difficult to influence by treatment, but one case recently observed showed some improvement as a result of treatment with massive doses of liver extracts. A fuller discussion of the matter is contained in an article in *Reports on the Chronic Rheumatic Diseases*, No. III, 1937. A pathological leucopenia is otherwise so rare in rheumatism that, if discovered, the case should be carefully reviewed for evidence of other disease.

LETTERS, NOTES, ETC.

An Exchange Scheme for Medical Students

Mr. A. D. LEIGH B.Sc., writes from Budapest: Thirty-three foreign students are gathered here in Budapest for the months of July and August. They are working at the different clinics attached to the Pázmány Péter Tudományegyetem (University), and represent seven countries. Sixteen students from Poland, both men and women, comprise the largest group; next come five Bulgarians, then four Letts, three Finns, two Frenchmen, two Austrians, and lastly the writer, who is the sole English representative. All are exchange students, an equal number of Hungarian medical students having travelled to the various countries concerned, where they also will work in hospitals and clinics. The Hungarian Medical Students Association is responsible for this scheme, and with very willing co-operation from the professors and their staffs in the clinics is making it a very great success. The foreign student is allowed to choose the clinic in which he would work, be it gynaecology, dermatology, internal medicine, surgery, etc. The two great clinics which form part of the University have an abundant supply of interesting material, and there are not more than two or three students in each section of the clinic. The Hungarians speak German, French, and English, so that there is no language difficulty, and a foreign student receives what is almost individual attention. A programme of visits to the various hospitals and clinics here has been arranged, and already the party has visited the Central Ambulance Station. To this station comes news of every accident in Budapest, and from it goes an ambulance carrying a student to the scene of the accident. The foreign students are to share in this work, and are looking forward to a spell of duty on the station. A display of films on first aid and life-saving was shown to the party, which also visited every section of the station. The balneological virtues of Budapest are well known, and a visit to the various medicinal baths is also to take place.

A Solecism

Dr. GEORGE S. BANKS writes from Aberdeen: Can nothing be done in the interests of orthology to discourage the continued use by some writers of the word "rheumatic" as qualifying clinics, committees, councils, etc.? The personnel of these may be rheumatic, no doubt many are in part explanation of their enthusiasm for the cause. Why not, on the same analogy, an Empire Anaemic Council; a Measly Commission, a Scabious Clinic, a Tuberculous Medical Officer, a Cancerous Research Committee?

Stammering

Dr. WM. RUSHTON PARKER writes: Stammering is a mere functional complaint like blushing and can be a grave handicap. When Lord Lister, in 1877, left Edinburgh for London I went to hear his introductory address, and I noticed at once that he was a stammerer, for I had been one myself in earlier days and understood the tricks; but I doubt if anybody else noticed it until he stumbled dreadfully over a difficult word, blushed crimson, and the latter half of the lecture became rather painful to listen to. Over twenty years ago I visited the Manchester Stammering School, to which every stammerer from the elementary schools is sent. I found thirteen boys and one girl being cured, and was told that over 90 per cent. of stammerers were boys and under 10 per cent. girls. Cure usually took three months, very few relapses occurred, and second relapses hardly ever. Considering the tremendous handicap which stammering becomes in after-life, I wonder why other large towns do not follow Manchester's example.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

Spontaneous Pneumothorax

107 M. R. CASTEX and E. S. MAZZEI (*Arch. méd.-chir. Appar. resp.*, 1937, **12**, 1, p. 23) point out that spontaneous pneumothorax may often appear in cases of pulmonary tuberculosis. The condition usually occurs in young men under the age of 30; in the authors' twelve cases, in all of which recovery took place, there were no women. Benign spontaneous pneumothorax may arise when the patient is at rest or as the result of varying degrees of physical effort. The onset may be insidious or sudden, and the outstanding symptoms are pain and dyspnoea, with palpitations, cold sweats, cyanosis, nausea, and vomiting. The intensity and duration of the pain is variable, and it may be localized or radiating. There is usually immobility of the affected side of the chest with diminution or absence of local fremitus, increased resonance, and loss of breath sounds. Radiology is of diagnostic value, as it establishes the extent of the pneumothorax and the degree of pulmonary collapse. The pneumothorax is usually complete when there are no adhesions present. Prognosis is good, the symptoms decreasing in intensity after a few days, and the patient recovering completely by the end of a month. The chief complications are haemorrhage and the simultaneous occurrence of the condition on both sides. Recurrence takes place in 10 to 20 per cent. of cases, in occasionally as often as fourteen times. Treatment consists of complete rest, morphine injections to relieve pain, and slow respiration. In cases of circulatory shock stimulants may be necessary, and if acute anoxaemia is present it is best to carry out extraction of the air and give oxygen.

Hodgkin's Disease

108 According to H. PRINZ (*Zbl. Chir.*, June 19, 1937, p. 1461) a large mediastinal tumour as an early manifestation in Hodgkin's disease is rare. However, it may occasionally cast a large *x*-ray shadow or even deform the chest wall before diagnosis is possible from enlargement of the lymph glands and spleen, together with irregular pyrexia and the results of biopsy. He relates the case of a girl, aged 15, in whom an anterior mediastinal swelling pushed forward the second and third left ribs; at operation for supposed primary neoplasm a tumour the size of a foetal head and weighing 315 grammes and adherent to the pericardium, left pleura, and chest wall was removed, with the exception of substernal prolongations adherent to the arch of the aorta and great veins. Microscopical examination showed it to consist of lymphogranulomatous tissue, to be rich in plasma cells and eosinophils, and to contain giant cells embedded in connective tissue. Deep *x*-ray treatment was subsequently carried out, and the patient recovered after fifteen months. No lymph-gland swelling was noted before or after operation.

Cardiac Tuberculosis

109 S. COHEN (*Amer. Rev. Tuberc.*, May, 1937, p. 618) reports that tuberculous pericarditis is found in 5 per cent. of patients dying from tuberculosis; tuberculosis of the myocardium is rare, about 0.25 per cent. of cases being found at necropsy; and the frequency of that of the endocardium has been estimated variously as from 0.6 to 90 per cent. in terminal tuberculous conditions. Both haematogenous and lymphatic infections are possible. Tuberculosis is the most common cause after rheumatic fever of chronic adhesive pericarditis, and in addition may often produce a chronic mediastinitis with venous obstruction—Pick's syndrome. Tuberculous pericarditis may cause no symptoms, or those of acute or chronic adhesive pericarditis, of which the tuberculous nature may be suspected if the presence of tubercle bacilli can be demonstrated elsewhere. The diagnosis of myocardial tuberculosis is rarely made, in some 50 per cent. of cases it gives rise to ectopic rhythm, and its presence may then be suspected in patients with lympho-haematogenous tuberculosis and tuberculous pericarditis. Cardiac tuberculosis seems especially common in the negro races, and it is associated with a protracted haematogenous infection, panadenitis, and panserositis. Two such cases are described by Cohen, in both of which the pericardium was primarily affected, probably by direct extension from caseous mediastinal lymph nodes. In the first there was caseous infection of all the cardiac chambers except the left auricle, and the great vessels of the heart were affected; there was also evidence of tuberculous (Poncet's) polyarthritis.

Surgery

Adamantinoma of the Lower Jaw

110 R. JAULAIN (*J. Méd. Bordeaux*, May, 29, 1937, p. 693) states that adamantinomata are very uncommon tumours, and are usually found in females over the age of 15. The adamantine epithelioma is most commonly situated on the posterior part of the horizontal ramus of the lower jaw. The first symptom is the gradual but steady increase in the size of the jaw, which causes a progressive deformity of the face. On palpation a fixed tumour can be felt; it may be hard, or, if cystic, fluctuation may be present. There are no functional symptoms in the early stages, and the general condition of the patient is good; diagnosis can be confirmed by radiography. The tumour, if neglected, may become as large as a foetal head, extending downwards to the chin. Sometimes the teeth erode the palate and fall out, speech and mastication become difficult, and gradually the general condition declines as a result of toxic absorption. If the tumour is cystic puncture will draw off a yellow or dark fluid, similar to that from an intracystic haemorrhage; while if it is hard radiography will often show destruction of the adjacent bone. Treatment must aim at complete removal, and this may be carried out in the early stages, when the lesion is localized, by curetting. In the case of large tumours extensive resection is necessary in order to prevent recurrence. A careful technique is needed for this operation, but even then bronchopneumonia is liable to develop. A case is reported in which a large tumour was successfully removed, but the patient died on the thirteenth day from pneumonia. Emphasis is laid on the importance of early treatment while the prognosis is still good.

Venous Thromboses

111 S. LINDGREN (*Uppsala LäkFören. Förh.*, May 31, 1937, p. 415) records two cases and refers to several others in the literature showing that deep venous thromboses of the legs may evoke a clinical picture practically indistinguishable from that of embolism of the femoral artery. His first patient was a woman, aged 25, who suddenly developed violent pain in the calf of the left leg a few days after she had been operated on for extra-uterine pregnancy. Numbness and cyanosis almost reaching to the groin soon developed. No arterial pulsation could be felt in this limb, which was cold and discoloured in patches and pitted on pressure, as well as being paralysed. Although there was nothing in the patient's history to support the diagnosis of embolism of the femoral artery,

it was explored under local anaesthesia on the assumption that it might have been blocked by an embolus. The operation revealed thrombosis of the femoral vein, and a femoral artery of which the dimensions were only about one-third of the normal. It was evidently reduced in volume by spastic contractions, which presumably subsided when, an hour after the operation, the leg again became warm, sensation returned to it, and the patient could move her toes again. The subsequent course of the case was uneventful. The author concludes that even when the onset of this type of thrombosis is not as violent as in the cases he records, it may yet be reflected in the behaviour of the neighbouring arteries; and in this connexion he notes that Professor Nyström has for several years found an aid to the early diagnosis of this form of thrombosis in the behaviour of the femoral pulse, which is weaker and smaller than that of the other leg; this phenomenon is demonstrable before the appearance of oedema, and is presumably due to spasmodic contraction of the femoral artery.

112 Familial Ankylosis of the Finger-joints

H. NOWAK (*Dtsch. med. Wschr.*, June 11, 1937, p. 937) reports from Vienna his observations on a family twenty-one of whose members presented some form or other of familial ankylosis of the finger-joints. According to Lenz this condition is characterized by stiffness of the little finger and often also of the ring finger, both of which are permanently flexed at the first and second phalanges. The corresponding flexor tendons are easily palpable and seem to be shortened. According to the same authority this deformity is frequently associated with syndactylism of both fingers and toes. Eleven of the author's twenty-one cases were males.

113 Congenital Prostatic Insufficiency

E. M. SIENKIEWICZ (*Z. Urol.*, 1937, **31**, 6, p. 400) describes in detail the different clinical and anatomical aspects of prostatic insufficiency, and comes to a number of conclusions. Almost every case of enuresis presents in later life some form of pronounced prostatic insufficiency. In a number of cases the cystoscopic examination may show the Alexeev-Schramm symptom—dysplasia of the trigonum, an annular sphincter, and occasionally the formation of valvular folds and of a vesico-urethral obstruction. Increased excitability of the detrusor and an insufficient trabeculation are less important in diagnosis. In other cases the history reveals some degree of failure of erection, an accelerated ejaculation, and a relative impotency. These disturbances usually become more accentuated with age, while the libido remains relatively unaffected.

Therapeutics

114 Prontosil in Erysipelas

K. MOTZFELDT (*Norsk. Mag. Laegevidensk.*, June, 1937, p. 630) reports from a hospital in Oslo his experience in the treatment of erysipelas; he classified his cases according to whether they were or were not treated with prontosil. In the pre-prontosil period 1924–35 there were 176 patients, of whom 106 were women. The average age was 34, and there were twelve deaths, an average mortality of 6.8 per cent. Three out of nine patients under the age of 1 and two out of eight over the age of 70 died; the average duration of the fever was nine days. Except for ten cases given a supposedly specific serum, the patients in this group received only symptomatic treatment. In the prontosil group there were twenty patients, all of whom, with only one exception, suffered from erysipelas of the face. The prontosil was given simultaneously by the mouth and by intramuscular injections. In every case the temperature fell to normal within two days after the first administration of prontosil, and the average duration of the fever in this group was between three and four days. The rash disappeared very quickly, the improvement in the general condition was remarkable, and there were no deaths.

115 Hydrotherapy

A. TANBERG (*Nord. med. Tidskr.*, April 24, 1937, p. 648), who is in charge of the Sandefjord Hydro in Norway, has applied the sedimentation test to his patients in different stages of hydrotherapy and has found that it remained unchanged in fifty-one cases, or 7.7 per cent. of the total number investigated. In 432 cases, or 65 per cent., the rate of sedimentation was slower, and in 181, or 27.3 per cent., it was quicker. Taking a normal rate as under 10 mm., he describes three main types of reaction according to whether the test remains unchanged at the end of treatment or whether there is slowing or quickening. When slowing occurs, the downward curve is comparatively uniform in the first five or six weeks, after which it tends to flatten out, a phenomenon which, in the author's opinion, shows that for the time being nothing more can be achieved by hydrotherapy. The higher the original rate of sedimentation the greater the proportion of cases in which treatment was associated with a slowing of the rate; in cases with an initial rate of 50 to 100 mm. up to 90 per cent. showed a slowing. A high rate need be no contraindication to hydrotherapy provided the patient is afebrile. It is exceptional for hydrotherapy to restore a high rate to normal; this happens most often after acute rheumatic fever or a prolonged attack of gout, or even after polyarthritis has been chronic for several years. In some cases the rate may still be the same at the end of treatment, although clinically the patients are better or worse, and it is not easy to draw instructive conclusions from the behaviour of this rate in every case. As abnormally high rates may range from 10 to 128 mm., and as the duration of the patient's illness may be from a few months to some thirty years, it is very difficult to discover the main principles governing the rate of sedimentation in the mixed material of a hydrotherapeutic institution.

116 H. URBAN (*Wien. klin. Wschr.*, June 4, 1937, p. 868) maintains that patients suffering from disorders of motility are capable of a considerable amount of movement and co-ordination when the affected parts are immersed in water. This form of therapy is suitable for patients suffering from disorders of the equilibrium and from spastic conditions following cerebral, spinal, or peripheral paralysis. It is economical since it saves time, and is also useful in the investigation of certain problems connected with disturbed motility.

Laryngology

117 Nasal Deformity

CLAOUÉ (*Réun. méd.-chir. Morphol.*, December, 1936, p. 166) points out the difficulty of correcting a saddle-back deformity of the nose. Various methods have been tried, including a cartilaginous costal graft, a bone graft, and the introduction of paraffin, india-rubber, or ivory. Of these the author's nine years' experience have convinced him that the use of an ivory graft is more satisfactory, and this method is discussed in detail. The most suitable type of ivory is that obtained from elephants. It must be fixed securely in position, and should then be carved into a suitable shape for correcting the deformity. Illustrations of this procedure are given. Intolerance to the ivory may be shown immediately after operation by the sloughing of the skin, or it may not appear until several months later, when the skin becomes red and inflamed. Fluctuation develops slowly, due to a collection of fluid round the graft, and is followed by secondary infection and

sloughing. This complication has been dealt with successfully by continued x-ray therapy, which improves the condition of the skin and brings about the absorption of the fluid and the disappearance of the inflammation.

118 Nasal Ulceration in Copper-plating Works

M. H. BARSKY (*N.Y. St. J. Med.*, June 1, 1937, p. 1031) states that he is the first observer to describe nasal disorders in relation to copper-plating. Ulcerations of the mucous membranes and perforation of the nasal septum associated with the use of chromium compounds in industry have been recognized for some time. Two employees in the copper-plating department complained of persistent running nose and epistaxis. On examination they were found to have shallow ulcerations of the septum and turbinates. Following this the departmental foreman became seriously ill with furunculosis of the nasal vestibule and ulceration of the nasal mucosa. The septic process spread, and in a short time he died from a terminal pneumonia. Fifteen other workmen were also slightly affected. The cyanide tanks used in copper-plating were blamed for the symptoms. Some time before this workmen in an adjacent department had complained of irritating vapour, and wooden partitions had been erected between the tanks in order to meet their objections. These restricted the natural ventilation, and as a result the corrosive spray arising from the copper-plating tanks became sufficiently concentrated in the atmosphere to produce the nose lesions. The plating department was shut down for several weeks, and various improvements were made in the ventilation. Also, by the use of additional floor boards, the heads of the workmen were raised a few inches higher than the tanks. Subsequently there were no recurrences of symptoms in the old workers, and none appeared in new employees.

119 Semicircular Canals

E. W. PEET (*J. Laryng.*, June, 1937, p. 431) describes certain variations in the anatomical relationships of the four vertical canals. Since Crum Brown's anatomical study of the semicircular canals in 1874 it has been held that the plane of the posterior canal on one side is parallel to that of the superior canal on the other. Consequently physiologists have assumed that the posterior canal of one and the superior canal of the opposite side function as a single unit, but since they are sensitive to movements of rotation in both directions about an axis at right angles to their common plane, Peet shows that these canals are very seldom parallel. The lines drawn in the planes of the osseous canals usually meet at an angle forward which varies from 15 to 20 degrees. In one extreme case of a skull with a high cephalic index the angle was 41 degrees; only one skull, that of a child, showed true parallelism. The article is illustrated by very clear photographs of the various skull bases from which these conclusions are drawn. Although these anatomical variations exist, the author considers that they are still compatible with the accepted theories of labyrinthine function.

120 Otocysts in Animals

BLANCO (*Ann. Oto.-laryng.*, March, 1937, p. 198) reviews the part played by the otocysts in the animal kingdom. These have been especially studied in fishes, where they lie near the surface. In many species of fish they are simple vesicles containing one otolith resting on the end-organ. So long as the fish swims in the normal position the otolith rests vertically on the end-organ, but as soon as it turns in any particular direction the otolith moves and presses on a different area of the end-organ. When the otocysts are destroyed by a needle-prick the fish's sense of orientation is abolished, and it may swim on the back or side, or turn about aimlessly. Certain crustaceae have otocysts which open externally by means of a valve. When the shell is shed the otoliths are also left behind, and the crab falls to the bottom of the tank. It then picks up fine particles of sand in its claws and places these inside the otocyst. Kreidl put fine particles of iron filings into the tanks and the animals placed some of these into their otocysts. Subsequently he placed a magnet in the tank. As long as this was beneath the animal there was no disturbance, but when it was placed above or to the side the animal turned on its own axis and assumed fresh positions according to the direction of the pull on the metallic otoliths. Another organ closely allied to the labyrinth and otocysts is the "swimming bladder," the function of which is to register the external pressure, and in many types of fish this is developed from the intestinal tract. When a fish with a visible swimming bladder is taken from a deep level of water and placed into a small tank the swimming bladder becomes dilated from the alteration in pressure. For many hours such an animal makes violent swimming efforts to reach a lower level until the pressure has adjusted itself again.

121 Pharyngeal and Oesophageal Diverticula

F. H. LAHEY and W. B. HOOVER (*New Engl. J. Med.*, April 8, 1937, p. 591) analyse fifty-three consecutive cases of operations for diverticula of the lower pharynx and upper oesophagus. Of these cases forty-three were men and ten women. The outstanding symptoms of this condition are difficulty in swallowing, regurgitation, gurgling noises, choking attacks, and loss of weight. The diagnosis can usually be made from the clinical history, but should be confirmed by a careful roentgenologic study. The x-ray examination also rules out other lesions of the oesophagus and ascertains the size, shape, and position of the sac. The operation for such diverticula is done in two stages. At the first operation the sac in the neck is completely freed, the encircling constrictors are carefully dissected and cut, and the dome of the diverticulum is then fixed high in the wound, so that it lies at a higher level than the opening into the oesophagus. This operation relieves the patient's symptoms at once; the second one takes place from eight to twelve days later, and the sac is then amputated. The authors recommend a special dissection of the mucosa from the submucosa; a small cuff of mucosa is pushed into the neck of the sac and the submucosa sewn over it, and in this way leakage can practically always be avoided. Most of the patients require post-operative dilatation, and this must often be continued for a year. In the authors' series good results were obtained in forty-nine cases, poor results in two cases, and two were failures.

Obstetrics and Gynaecology

122 Insufflation of the Tubes

L. BONNET (*Presse méd.*, May 12, 1937, p. 715) is of the opinion that kymographic insufflation of the tubes is a procedure which is of value in obtaining records of the intratubular pressure during insufflation. By this means the permeability of the tubes can be ascertained and records of the contractions of the tubes obtained, making possible an estimate of their functional capacity and to some extent that of the ovaries. In cases of tubular sterility insufflation has been the first procedure, followed by the injection of lipiodol in doubtful cases or when the exact position of the obstruction must be known for surgical treatment. It has been found, however, that kymographic insufflation gives even better and more detailed information than does lipiodol injection. During insufflation of a normal tube by a current of gas, rhythmical peristaltic movements can be registered and variations of pressure recorded on the drum. If the tube is permeable

the graph shows a series of more or less irregular oscillations with a pressure of from 60 to 70 mm. of mercury—never above 100 mm. When the tube is obstructed the passage of gas is stopped when the pressure reaches 200 mm. of mercury. When tubular spasm occurs the pressure passes 100 mm. and may reach 200 mm., but as soon as the spasm ceases the pressure falls rapidly until the oscillations are similar to those of a normal tube. In cases in which a tube is stenosed, either by lesions of the mucosa or by peritubular adhesions or torsion, the pressure rises up to 100 to 200 mm. of mercury and then falls gradually with little or no oscillation. From these results it has been possible to evaluate ovular function, which is in direct relation to tubular function. A case of ovarian insufficiency showed a pressure of only 10 mm. of mercury, but after x-ray or radium treatment the number and amplitude of the oscillations increased markedly. Following insufflation of tubes not completely obstructed pregnancy resulted in nearly 25 per cent. of cases.

123 Milk Fistula treated by Follicular Hormone

S. ERNST (*Zbl. Gynäk.*, June 12, 1937, p. 1420) reports the excellent therapeutic results obtained from the administration of follicular hormone in two cases of milk fistula of the breast caused by mastitis. A number of other therapeutic measures were tried, without effect. The hormone was then administered as an injection of 50,000 [illegible] oleosum followed by daily doses of [illegible] taken in tablet form. The flow of milk stopped after a few days and the fistula was soon closed.

124 Caesarean Section

A. G. SCHULZE (*Minnesota Med.*, May, 1937, p. 282) notes that the incidence of Caesarean section varies from 1 to 3.25 per cent. at different hospitals. In the cases reviewed the maternal mortality varied between 5 and 10 per cent. Maternal morbidity was very much influenced by the type of operation performed, the pre-operative care of the patient, and other contributory factors. The tendency towards conservative treatment of the toxaemic patients is on the increase, probably in view of the high mortality—of from 20 to 50 per cent.—of Caesarean section in eclampsia. At the same time the classical Caesarean section is being rapidly displaced by the low or cervical type of operation, for although the classical section is the easiest to perform it shows the highest mortality and morbidity. The extraperitoneal type of operation presents no advantages.

125 *Folliculin Treatment of Pruritis*

G. COTTE and A. MILEFF (*Gynécologie*, April, 1937, p. 195) point out that it is only in the human vagina that the secretion is acid (*p*H 4.5 to 5.6) and contains Döderlein's bacillus, and that the wall contains glycogen. The inference that the bacillus forms lactic acid from the glycogen has been widely accepted, and it is now generally admitted in addition that the content of glycogen is dependent on ovarian activity. Nevertheless, in senility or after castration some glycogen remains. In hyperhormonal ameorrhoea, as the writers have found by biopsy, the vaginal epithelium attains an extreme thickness, while in amenorrhoea associated with infantilism it is greatly reduced. Folliculin treatment—either general or locally by inunction—has been used with success by a number of German observers in pruritus or kraurosis vulvae, on the assumption that the senile atrophy of the epithelium is countered by such hormone therapy. Cotte and Mileff proved by biopsy, in a woman, aged 68, who was suffering from severe pruritus, that in the atrophic epithelium of the posterior fornix the functional layer had practically disappeared and the basal layer was inactive, although it still contained traces of glycogen. After intramuscular injection of 40 milligrammes of oestradiol benzoate during eight days the itching disappeared and the epithelium became four or five times thicker, showing cellular activity in the functional and basal layers and glycogen in both.

Pathology

126 Blood Grouping and Compatibility

P. HOXWORTH and A. AMES (*J. Amer. med. Ass.*, April 10, 1937, p. 1234) describe a technique for blood grouping and matching which combines the principles of the Vincent and Coca methods and for which the following advantages are claimed. Both grouping and compatibility tests require only ten drops of defibrinated blood from finger punctures, and venepuncture is avoided. The blood group is usually obvious in less than one minute, provided that standardized test sera of high titre are used, and compatibility may be determined in fifteen minutes and the conditions of the proposed transfusion can be reproduced *in vitro* both qualitatively and quantitatively. Universal donors with agglutinin titres dangerous to A or B recipients can be detected, and low-titred A donors may be selected for universal recipients. Grouping is determined by mixing defibrinated blood with large drops of anti-A and anti-B test sera of high titre on a glass slide. Agglutination, when it occurs, is complete in less than one minute. If there is none by this time the slide is covered to prevent drying and observed after fifteen minutes in order to guard against weak agglutinogens. For matching purposes a 50 per cent. dilution of the recipient's defibrinated blood in normal saline is mixed on a slide with one-fifth of its volume of similarly diluted defibrinated donor's blood. The slide is covered to prevent evaporation, and after fifteen minutes it is observed under low-power magnification. Unless the agglutination is so definite that there is no question of confusion with rouleaux formation, the blood may be pronounced compatible. The new techniques, after being checked with parallel determinations by the older methods in 200 cases with complete agreement, were used in 400 subsequent cases without a single reaction due to incompatibility.

127 Experimental Tumour Immunity

A. BESREDKA and L. GROSS (*Paris méd.*, June 5, 1937, p. 506) have investigated the possibility of non-specific immunization of rabbits and mice against malignant tumours. Injections of extracts of spleen, liver, kidneys, skin, and mouse embryo, and of emulsions of sarcoma rendered avirulent by heating, etc., did not protect mice against the induction of sarcoma by injections of emulsions of mouse sarcoma. Injections of emulsions of normal rabbit spleen also failed to protect them, while emulsions of normal rabbit brain in about half of the cases did protect the rabbits against the development of relatively benign intradermal epitheliomas following intradermal inoculation of an emulsion of Brown-Pearce's epithelioma. Injections of normal organs, however, failed to protect rabbits against the development of tumours in positions where they are most malignant—namely, subcutaneous, intraperitoneal, intraocular, intratesticular, and on the dura mater. The authors conclude that emulsions of normal organs have only an inconstant protective action against benign tumours and none at all against malignant tumours. In investigating the question of protection against malignant tumours they found that rabbits, in which they had induced experimental intradermal Brown-Pearce epitheliomas that had been afterwards spontaneously absorbed, had developed a stable, strong resistance against injections of emulsions of the epithelioma in places where a malignant tumour usually followed the injection. Serum antibodies responsible for this immunity could not be demonstrated by inoculation or parabiosis experiments. The authors infer, therefore, that the mechanism of the immunity is located in the epithelial lymphatics.

MALE HORMONE THERAPY

PERANDREN "CIBA"

The first synthetic, chemically pure hormone derived from Cholesterol. Standardised to contain about 50 I.U. per 1 mg.

Ampoules of 1·1 c.c., each containing 5 mg. testosterone propionate, in boxes of 4.

ANDROSTIN "CIBA"

Total testicular extract, physiologically standardised, containing the hydrosoluble and liposoluble fractions.

Tablets in bottles of 30. Ampoules in boxes of 6.

Indications: Testicular insufficiency, impotence, premature senility, obesity of endocrine origin, climacteric of man, prostatic hypertrophy, neurasthenia in man and woman, acne in young women.

SHOP WINDOWS

Who is not tempted to glance at the goods displayed in the shop windows which brighten the streets of every town? The subtle attraction of articles thus brought to notice cannot be explained by any immediate need to purchase. Indeed, the majority of the contents of shop windows have no immediate appeal. They are seen and a mental note is made which may well prove useful later on.

So it is with the advertisements in the *British Medical Journal*. Sometimes, it is true, the reader searches these pages to find a particular preparation or appliance for use in the treatment of a specific case. More often the advertised products are noticed and remembered pending their being required at some future time.

In this way an up-to-date knowledge of proprietary aids to medical practice can be maintained without expense and with very little expenditure of time.

Two helpful suggestions: Pages may be cut out and filed for future reference, and it is always worth while to mention the B.M.J. when writing to advertisers

THE IDEAL ANTACID

Magnoleum is an emulsion of liquid paraffin and magnesium hydroxide prepared entirely by mechanical means without the aid of any constipating mucilaginous emulsifying agents. Its action is that of its active ingredients in an extremely fine state of sub-division. Being perfectly miscible with water or milk it may be diluted before taking, given to bottle-fed infants in food, etc. It is readily acceptable to children and delicate or fastidious adults.
Issued in convenient wide mouthed glass bottles, 1/3 and 2/6. Write for specimen for clinical trial.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashire. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

Tel.: 64117. For terms, etc., apply to the Medical Superintendent.

HAYDOCK LODGE

NEWTON-LE-WILLOWS, LANCASHIRE

Teleg.: Street, Ashton-in-Makerfield *'Phone*: Ashton-in-Makerfield 7311.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES suffering from mental and nervous diseases, either voluntarily, temporarily, or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, near EXETER,

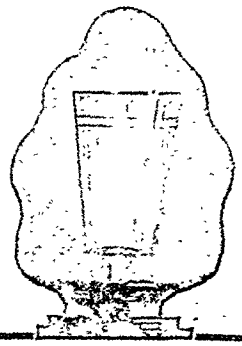
Choose a Spa in Czechoslovakia...

The Spas and Health Resorts of Czechoslovakia, with their centuries-old tradition of healing, reinforced by the experience and researches of local specialists, invite your serious consideration.



In addition to places of world-wide repute such as

PISTANY (Piestany) **CARLSBAD** (Karlovy Vary) **MARIENBAD** (Marianske Lazne) **FRANZENSBAD** (Frantiskovy Lazne)

ST. JOACHIMSTHAL (Jachymov) **TEPLICE-SANOV** (Teplitz-Schönau) **LUHAČOVICE** **SLIAC** **TRENČIANSKE-TEPLICE**

with their medicinal springs and mud baths, there are numerous smaller spas and health resorts admirably equipped for the treatment of many diseases, including those in the following groups:

ANAEMIA AND CHLOROSIS
BASEDOW'S DISEASE.
BRONCHIAL CATARRH.
CONSTITUTIONAL DISEASES, SCROFULA, RICKETS.
DIGESTIVE DISEASES.
DISEASES OF THE BLADDER AND URINARY ORGANS.
DISEASES OF THE KIDNEYS.
DISEASES OF THE NOSE AND THROAT.
DISEASES OF WOMEN.
DISORDERS OF BONES, MUSCLES, AND JOINTS.
DISORDERS OF THE HEART.
DISORDERS OF METABOLISM AND GOUT
GALLSTONES.
LEUCAEMIA.
NERVOUS DISEASES AND POST HEMIPLEGIC CONDITIONS.
TUBERCULOSIS OF THE LUNGS

The arrangements in the bath establishments are up-to-date in every way, the cleanliness and neatness proverbial, the service attentive and courteous.

It is accepted that a spa cure to be fully beneficial should provide a complete change of surroundings, and a break with the patient's normal everyday life.

The Czechoslovak Spas fulfil this purpose admirably . . . comfortable hotels . . . first-class orchestras and dance bands . every facility for sport—tennis, golf, swimming, riding, fishing, etc.

There are also numerous fully up-to-date homes for convalescence and rest cures.

LONDON HOSPITAL MEDICAL COLLEGE

PRIMARY FELLOWSHIP EXAMINATION.

A COURSE OF INSTRUCTION for the above Examination will begin on Wednesday, Sept. 1st. The fee for the Course is 15 guineas.

Further particulars may be obtained from Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S., Dean, Turner Street, Mile End, E.1.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL

THE WINTER SESSION will Open on Friday, October 1st.

The LONDON HOSPITAL serves the East End of London, and with eight hundred and fifty beds is the largest voluntary Hospital in England. The Out-patient Department, which deals with a hundred thousand new patients per annum, is extensively used for teaching.

The size of the Hospital necessitates a large number of resident medical officers. Every year seventy resident house physicians and house surgeons and eighty salaried non-resident clinical assistants are appointed from among recently qualified students. The opportunities which these appointments offer for obtaining clinical experience is invaluable.

The MEDICAL COLLEGE is attached to the Hospital and is staffed by Professors of Anatomy, Physiology, Bacteriology, Chemical Pathology, Morbid Anatomy and Medicine of the University of London.

SPECIAL COURSES in Anatomy and Physiology for the Primary F.R.C.S. and Advanced Courses in Surgery for the Final F.R.C.S. Examination, and in Medicine for the M.D. and M.R.C.P. Examinations, are held twice a year.

ENTRANCE SCHOLARSHIPS AND PRIZES of the total value of £950 are awarded annually. Research Funds to the value of £113,000 permit of assistance being given to students and graduates engaged in medical research.

The MEDICAL COLLEGE contains a modern Museum of Pathology and a Library provided with all the current medical periodicals in charge of a full-time librarian. There is also an Athenaeum Club and Dining Hall, a Gymnasium, a Fives Court, and two Squash Courts in the Students' Hostel. The Athletic Ground of 13 acres at Hale End is within easy distance of the Hospital.

The HOSPITAL is only 20 minutes from Charing Cross and Baker Street Stations. For those who wish to live in immediate proximity to the Hospital there is accommodation for sixty students in the Students' Hostel.

Further details may be obtained from the Dean, Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S., or from the Sub-Dean, Dr. A. E. CLARK-KENNEDY, M.D., F.R.C.P., Physician to the Hospital and Fellow of Corpus Christi College, Cambridge, who are always pleased to meet students wishing to see the Hospital and College. Application for admission should be made to the Dean.

Turner Street, London, E.1.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL

MARYLEBONE ROAD, N.W.1

Medical Students and Qualified Practitioners admitted to the Practice of this Hospital. Unusual opportunities are afforded of seeing Obstetrical Complications and Operative Midwifery (about one half of the total admission being primiparous cases). Over 2,700 patients are admitted to the Wards annually, and in the Ante-natal Department there are over 20,000 attendances per annum. Clinical demonstrations are given by the Staff daily.

For rules, fees, etc., apply H. B. STOKES, Secretary-Superintendent.

CITY OF LONDON MATERNITY HOSPITAL

(Incorporated by Royal Charter)
CITY ROAD, LONDON, E.C. 1

COUNTY BOROUGH OF SUNDERLAND EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER.

Applications from qualified medical practitioners are invited for the post of Assistant School Medical Officer (man), at a salary at the rate of £600 per annum, advancing by annual increments of £25 to a maximum of £700.

Applicants, since qualification, should have:

(1) Had at least three years' experience of the practice of medicine.

(2) Held an appointment gaining practical experience in the use of a modern x-ray plant for diagnostic and treatment purposes, and also experience in the use of ultra violet rays. A Diploma in Radiology will be an advantage.

Preference will be given to applicants who:

(1) Have had some experience of school medical work.

(2) Have enjoyed opportunities for the study of diseases of children.

The candidate appointed will be required to devote the whole of his time to the duties of the office.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination.

Forms of application may be obtained from the undersigned, to whom they should be returned not later than Monday, August 23rd, 1937.

Canvassing will be a disqualification.

W. THOMPSON,
Director of Education.

Education Offices,
15, John Street,
Sunderland.
July, 1937.

CITY OF COVENTRY.

CITY ISOLATION HOSPITAL

RESIDENT MEDICAL OFFICER

Applications are invited from duly qualified and registered male medical practitioners (preferably married) for the post of Resident Medical Officer at the City Isolation Hospital (148 beds). The hospital is modern and a suitable house for the R.M.O. is provided.

Applicants should have had special experience in the diagnosis and treatment of infectious diseases, and experience in the treatment of venereal diseases will be deemed an additional qualification.

The salary will be at the rate of £250 per annum increasing subject to satisfactory service by biennial increments of £50 to £350 per annum plus emoluments (house, fuel, and light) valued at £150 per annum.

The post is designated under the Local Government and Other Officers' Superannuation Act 1922, as amended in regard to annuities to widows by the Coventry Corporation Act 1936, and the successful applicant will be required to pass a medical examination as to fitness and to contribute to the superannuation fund. The successful applicant will also be required to contribute to the Coventry Staff Widows' and Orphans Pension Fund.

Application (on the prescribed form which is obtainable on request) together with copies of three recent testimonials must reach the undersigned on or before August 20th 1937.

A. MASSEY
Medical Officer of Health

The Council House,
Coventry
July 23rd, 1937

CITY OF CARLISLE

Appointment of ASSISTANT MEDICAL OFFICER for MATERNITY and CHILD WELFARE.

Applications are invited from medical women to take charge of the Corporation Maternity Home (12 beds). Ante natal, Post natal, and Infant Clinics. The duties will also include School Medical Inspection, Supervision of Midwives, and such other Public Health duties as may from time to time be prescribed. The duties of the respective offices will be carried out under the direction of the Medical Officer of Health.

Applicants must have had at least two years' experience as Maternity and Child Welfare Medical Officer, and should be in possession of the Diploma in Public Health, and preference will be given to candidates who have a special qualification in Midwifery.

The commencing salary will be at the rate of £600 per annum, rising by annual increments of £25 to a maximum of £700 per annum, and the lady appointed will be expected to commence duty at about the beginning of November.

The appointment is subject to the Local Government and Other Officers' Superannuation Act, 1922.

Applications, endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, should be submitted to the Medical Officer of Health, 22, Fisher Street Carlisle on or before August 18th, 1937.

By Order,
FREDK. G. WEBSTER,
Town Clerk.

Town Clerk's Office, Carlisle
July 13th. 1937

HULL CORPORATION HEALTH DEPARTMENT.

Hull Municipal Maternity Home and Infants' Hospital (104 Beds).

JUNIOR RESIDENT MEDICAL OFFICER (WOMAN)

Applications are invited from unmarried or widowed Women Medical Practitioners for the appointment of Junior Resident Medical Officer at the above Institution.

Salary £100 per annum, together with board, washing and residence at the Maternity Home.

The appointment will be for six months, with a possible extension for a further period of six months.

Applications, on forms to be obtained from the undersigned, are returnable not later than noon on Thursday, August 12th, 1937.

NICOLAS GEBBIE, M.D.,
Medical Officer of Health

Health Department,
Guildhall, Hull.
July, 1937.

NEW SUSSEX HOSPITAL FOR WOMEN, WINDLESHAM ROAD, BRIGHTON

(60 Beds)

Applications are invited from medical women for the post of HONORARY SURGEON to the New Sussex Hospital. The Senior Assistant Surgeon is an applicant for the post, and in the event of her election an Assistant Surgeon will be required. Candidates should possess the F.R.C.S. or equivalent qualification.

Copies of three recent testimonials to be sent to the Secretary on or before September 14th.

P. F. SPOONER,
Secretary.

Board Room,
Windlesham Road, Brighton.

SOUTHERN RHODESIA MEDICAL SERVICE.

GOVERNMENT MEDICAL OFFICER.

Applications are invited from single, fully qualified male Medical Practitioners for appointment as a Government Medical Officer in the Southern Rhodesia Medical Service.

Salary will be on the scale £660—£25—£750 per annum. There is also a senior grade (£750—£25—£900) to which promotions are made as vacancies occur. Salary will commence from the date of assumption of duty in Southern Rhodesia. In addition, private practice is allowed.

The successful applicant will be required to sign an agreement for three years' service in the first instance, and thereafter may make application to be placed in the pensionable establishment.

A free second-class steamship passage to Cape Town and first-class railway ticket thence to Southern Rhodesia will be provided.

Canvassing either directly or indirectly, will disqualify applicants.

The applicants should state the date on which they would be prepared to leave England if appointed.

Applications, stating age, qualifications and experience, together with copies of testimonials, should reach the Official Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (from whom further particulars and application form may be obtained) not later than August 21st 1937.

LANCASHIRE MENTAL HOSPITALS BOARD

APPOINTMENTS OF MEDICAL SUPERINTENDENTS

Applications are invited for the following whole-time appointments:

Medical Superintendent, County Mental Hospital, Lancaster (vacant on September 30th next).

Medical Superintendent, County Mental Hospital, Winwick, near Warrington (vacant on October 31st next).

The salary in respect of each appointment is £950 per annum, rising by annual increments of £100 to a maximum salary of £1,350 per annum, together with emoluments valued at £150 per annum.

The appointments will be subject to the provisions of the Asylums Officers' Superannuation Act, 1909.

Applicants are required to submit their applications on a form to be obtained from the undersigned, and applications endorsed "Medical Superintendent, Lancaster Winwick," as the case may be, should be sent to or delivered at my office not later than 12 noon on Wednesday, September 1st, 1937.

Canvassing either directly or indirectly, will be a disqualification.

GEORGE ETHERTON,
Clerk of the Board.

County Offices,
Preston
July, 1937

HERTFORDSHIRE COUNTY COUNCIL. PUBLIC ASSISTANCE.

COUNTY INSTITUTION, OSTER HOUSE, ST. ALBANS.

HOUSE SURGEON.

Applications are invited for the post of House Surgeon (either sex) at the above Institution, which comprises general medical and surgical wards, with separate Maternity and Children's Units.

Salary will be at the rate of £175 per annum, with an allowance of £3 3s per week until such time as board and residence can be provided in the Institution. The appointment will be limited to one year and not renewable. The House Surgeon must, until quarters in the Institution are provided, reside near the Institution at an address to be approved by the Guardians' Committee.

Candidates must be duly qualified and registered.

Applications, stating age, qualifications and experience, with copies of not more than three recent testimonials, should be sent to the Clerk of the St. Albans Guardians' Committee, Oster House, St. Albans (from whom any further details may be obtained) as soon as possible.

ELTON LONGMORE,
Clerk of the County Council.

Hertford.
July 30th, 1937.

PUBLIC HEALTH DEPARTMENT. CITY OF CHESTER

CITY HOSPITAL

JUNIOR RESIDENT MEDICAL OFFICER required for the above general hospital.

Salary will be £200 per annum, with full residential emoluments. The appointment will be for one year.

The successful candidate will be required to take up duties on October 1st.

Applications, stating age, qualifications and previous experience, together with copies of three recent testimonials, should be sent to the Medical Officer of Health, Town Hall, Chester, by Wednesday, August 18th.

J. H. DICASON,
Town Clerk.

ERITH URBAN DISTRICT COUNCIL.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Council of the Urban District of Erith invite applications from Medical Practitioners, of not less than three years' standing in their profession, for the above appointment.

The commencing salary will be determined by previous experience, with a minimum of £500 per annum and a maximum of £600 per annum. Annual increments of £25 will be given to a maximum salary of £700 per annum.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

The appointment will be determinable by three months' written notice on either side, and will also be subject to the Council's Standing Orders, Regulations and Resolutions governing staff.

The appointment is a whole time one. The duties will consist mainly of work in the School Medical Department, but will include, also, duty in any section of the Health Services of the Council.

Experience in the certification of mental defectives, in ante-natal care, and the possession of a registrable qualification in Public Health will be considered additional recommendations.

Applications, accompanied by copies of not more than three recent testimonials, must be made on forms obtainable from the Medical Officer of Health, Council Offices, Erith, to whom they should be returned to reach him not later than August 17th, 1937, endorsed "Assistant Medical Officer of Health."

Canvassing, either directly or indirectly, will disqualify.

DOUGLAS S. TWIGG,
Council Offices, Erith. Clerk to the Council.
July 30th, 1937.

LANCASHIRE COUNTY COUNCIL.

PARK HOSPITAL, DAVYHULME, NEAR MANCHESTER.

APPOINTMENT OF SENIOR RESIDENT MEDICAL OFFICER.

Applications are invited from registered Male Medical Practitioners for the appointment of Senior Resident Medical Officer at the above Hospital. Candidates must be unmarried. The appointment is for one year.

Salary £350 per annum, together with the usual residential allowances.

The Hospital comprises 500 beds for acute cases, is fully equipped in every respect, and is recognised as a complete Training School for Nurses.

The appointment will be terminable by one month's notice on either side.

Forms of application may be obtained from the COUNTY MEDICAL OFFICER OF HEALTH, Hospital and Medical Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded so as to be received not later than Saturday, September 4th, 1937.

County Offices, GEORGE ETHERTON.
Preston. Clerk of the County Council.
July 29th, 1937.

LANCASHIRE COUNTY COUNCIL.

JUNIOR ASSISTANT MEDICAL OFFICER, WRIGHTINGTON HOSPITAL, APPLEY BRIDGE.

Applications are invited for the post of Junior Assistant Medical Officer (male, unmarried) for the Wrightington Hospital, which contains 206 beds for non-pulmonary tuberculosis (adults and children) and 20 beds for "combined" pulmonary and non-pulmonary cases. Salary £200 per annum, together with board, residence and laundry. The appointment will commence on October 1st or thereabouts, and will be for twelve months.

The medical staff consists of medical superintendent, two assistants, two consultant orthopaedic surgeons, and other visiting surgeons. There are excellent facilities for reading for M.D.

Forms of application and conditions of appointment obtainable from CENTRAL TUBERCULOSIS OFFICER, County Offices, Preston. Letters to be marked "Wrightington M.O."

Closing date August 28th.

County Offices, GEORGE ETHERTON.
Preston. Clerk of the County Council.

LANCASHIRE COUNTY COUNCIL.

TEMPORARY ASSISTANT TUBERCULOSIS OFFICER.

A temporary Assistant Tuberculosis Officer required from September 1st until the end of November. Duties comprise dispensary sessions, home visitation of patients, and visits to County sanatoria. Car essential; mileage fee payable, plus personal allowance; live out. Salary, 15 guineas weekly.

Applications, stating tuberculosis experience, to Central Tuberculosis Officer, County Offices, Preston, Lancs.

CARMARTHENSHIRE COUNTY COUNCIL.

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from registered medical practitioners for the post of whole-time Assistant County Medical Officer of Health (male). Applicants must not be over 35 years of age, and must possess the Diploma in Public Health.

Salary £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum, plus £100 per annum for travelling expenses. The post is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the successful candidate passing a medical examination.

The successful candidate, who will be under the direction and control of the County Medical Officer of Health, will be required to reside at Carmarthen and to carry out such duties as may from time to time be imposed upon him by the County Medical Officer. The duties for the present will comprise those in connexion with the School Medical Service, but general public health work will be allocated later on.

The appointment will be held during the pleasure of the Council, and will be determinable by the Officer by three months' notice in writing.

A form of application can be obtained from the undersigned, which must be returned, together with copies of three recent testimonials, not later than August 31st, 1937.

County Offices, DANIEL JOHNS,
Carmarthen. Clerk of the County Council.
August 1st, 1937.

BOROUGH OF STRETFORD.

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified medical practitioners for the whole-time appointment of Assistant Medical Officer of Health and Assistant School Medical Officer at a commencing salary of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum.

Applicants must have had at least three years' experience in the practice of their profession subsequent to obtaining a registrable qualification, and must also hold the Diploma in Public Health.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

The terms and conditions of appointment, together with form of application, may be obtained from the Medical Officer of Health, Town Hall, Stretford, and all applications must be received by the undersigned not later than August 21st, 1937.

Town Hall, C. TREWAVAS,
Talbot Road, Stretford. Town Clerk.

LIVERPOOL PORT SANITARY AUTHORITY.

ASSISTANT PORT MEDICAL OFFICER.

The Corporation of the City of Liverpool, as Port Sanitary Authority, require the services of an Assistant Port Medical Officer, whose duties will be in connection with the tidal inspection of vessels, the medical inspection of aliens, and such other duties as may from time to time be assigned to him.

The salary will be £700 per annum.

Candidates, whose age shall not exceed 35 years, must possess a registrable medical and surgical qualification, and should hold a Diploma in Public Health.

The person appointed will be required to devote whole-time services to the duties specified and must reside within the city.

Canvassing of members of the Committee or the City Council will be considered a disqualification.

Form of application and details as to the duties may be obtained from the MEDICAL OFFICER OF HEALTH, Municipal Annexe, Liverpool, 2.

Applications, together with copies of not more than three recent testimonials, to be addressed to the undersigned so as to be received not later than August 31st, 1937. Envelopes to be endorsed "Assistant Port Medical Officer."

Municipal Buildings, W. H. BAINES.
Liverpool, 2. Town Clerk.

METROPOLITAN BOROUGH OF HAMPSTEAD.

MEDICAL OFFICER TO MUNICIPAL POST-NATAL CLINICS.

Applications are invited from registered medical practitioners (female) having special experience in post-natal work.

The successful applicant will be required to devote two sessions (approximately two hours each) per week to this work, and the remuneration will be at the rate of 1½ guineas per session.

Forms of application and further particulars of the appointment may be obtained from the Medical Officer of Health at the Town Hall. Completed application forms must be forwarded to the undersigned not later than Tuesday, August 31st, 1937.

Town Hall, P. H. HARROLD,
Haverstock Hill, N.W. 3. Town Clerk.
July, 1937.

ROWLEY REGIS BOROUGH COUNCIL.

DEPUTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Female).

The Council of the Borough of Rowley Regis invite applications for the above whole-time appointment from duly qualified Registered Medical Practitioners holding a Diploma of Public Health and not over 40 years of age. The officer appointed must have had experience in Maternity and Child Welfare, Pre-natal and School Medical Work, and must possess the necessary qualifications to act as Medical Supervisor of Midwives. The salary will be £600, and will rise, subject to satisfactory service, by annual increments of £25 to £700 per annum, and travelling expenses, in accordance with the Council's scale, will be allowed.

Candidates must apply on the prescribed form, to be obtained from Dr. Frank Asker, Medical Officer of Health, Haden Hill Park Offices, Old Hill, Staffs, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than Monday, August 23rd, 1937.

Council Offices, C. BUCKLEY,
Old Hill, Staffs. Town Clerk.

STAFFORDSHIRE COUNTY COUNCIL. WORDSLEY PUBLIC ASSISTANCE INSTITUTION.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered medical practitioners (male) for the post of Assistant Medical Officer (Resident) at Wordsley Public Assistance Institution, near Stourbridge. Salary £300 per annum, with board, residence and laundry. Candidates should be unmarried.

The appointment will be, in the first instance, for a period of six months, but the successful candidate will be eligible for reappointment for a further period of six months.

The Institution is in process of conversion into a Hospital, and facilities will be available for gaining experience in medicine, surgery, midwifery, and diseases of children.

Further details may be obtained on application to the County Medical Officer of Health.

Applications, stating age, qualifications and experience, with copies of testimonials, should be sent to the undersigned not later than Thursday, August 19th, 1937.

County Buildings, H. L. UNDERWOOD,
Stafford. Clerk of the County Council.
July 30th, 1937.

COUNTY BOROUGH OF READING. BATTLE HOSPITAL.

APPOINTMENT OF RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered medical practitioners for the appointment of Resident Assistant Medical Officer (male) at the above Hospital, at a salary of £300 per annum, with board, residence, etc.

Candidates must be single, and should not be more than 30 years of age.

The selected candidate will be required to work under the direction of the Medical Superintendent.

The appointment will be for a period of one year, and preference will be given to candidates who are reading for higher qualifications.

Forms of application may be obtained from, and must be returned duly completed to, the undersigned, with copies of three recent testimonials.

Canvassing, either directly or indirectly, will disqualify.

Town Hall, C. S. JOHNSON,
Reading. Town Clerk.
July 31st, 1937.

NORTHAMPTON COUNTY BOROUGH EDUCATION COMMITTEE.

ASSISTANT SCHOOL DENTIST.

Applications are invited for the appointment of a fully-qualified Dental Surgeon as Assistant School Dentist. Salary £450 per annum.

Further particulars and forms of application may be obtained from the undersigned, by whom applications should be received by not later than August 20th, 1937.

H. C. PERRIN, Secretary for Education, Education Office, "Springfield," Cliftonville, Northampton

BECKETT HOSPITAL AND DISPENSARY. BARNSLEY. (153 Beds. 3 Residents.)

Applications are invited for the post of JUNIOR HOUSE SURGEON (male), General Surgical, Ear, Nose and Throat Gynaecology, and anaesthetics. Candidates must be fully qualified and registered.

Salary, £200 per annum, with board, residence and laundry.

Applications, stating age, qualifications, accompanied by testimonials, should be addressed to the undersigned immediately.

ARTHUR L. BOURNE,
Secretary-Superintendent.
August 3rd, 1937.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in October, 1937.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than August 31st, 1937.

CITY OF BIRMINGHAM.

SELLY OAK HOSPITAL (520 Beds).

RESIDENT GYNAECOLOGIST AND OBSTETRICIAN (male).

Applications are invited for the above whole-time appointment from fully qualified registered medical practitioners who have had good experience in Gynaecology and Obstetrics, and who are Fellows of the Royal College of Surgeons (England).

Furnished quarters, rations, laundry and attendance will be provided, or alternatively a cash allowance will be paid if the officer appointed should be non-resident.

Salary will be £700, rising by annual increments of £50, to a maximum of £1,000 per annum, together with the emoluments stated above.

The appointment will be dependent on the candidate passing a medical examination and be subject to the Birmingham Corporation's Superannuation Scheme; and the Birmingham Municipal Officers' Widows' and Orphans' Pensions Scheme (if applicable). The appointment will be terminable by one month's notice on either side. The officer appointed will be required to refund to the Council all fees and allowances received in connexion with his duties.

Further particulars of the appointment may be obtained from the Medical Superintendent of the Hospital.

Applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, and endorsed "Gynaecologist and Obstetrician," should be sent to the Medical Superintendent not later than August 21st, 1937.

The Council House, Birmingham. F. H. C. WILTSHIRE, Town Clerk.

CITY OF BRADFORD.

MALE ASSISTANT CITY PATHOLOGIST required.

Salary £500 per annum, rising to £700 per annum by annual increments of £25.

The salary is subject to a deduction of 5 per cent. under the terms of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a satisfactory medical examination.

Application forms may be received from the Medical Officer of Health, Town Hall, Bradford, and should be delivered to the undersigned not later that August 31st, 1937.

Town Hall, Bradford. N. L. FLEMING, Town Clerk.

AMENDED ADVERTISEMENT.

CITY OF BIRMINGHAM.

ASSISTANT MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

The Public Health Committee invite applications from Medical Officers (Women) in connexion with the Maternity and Child Welfare Scheme.

Applicants must have held a six months' appointment as Physician in a Children's Hospital, and also held a six months' resident appointment in a Maternity Hospital. It is desirable that applicants should hold the Diploma in Public Health, and if they have not already obtained the Master of Midwifery Diploma they may be required to do so within a subsequent period. The salary will be £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum. The appointment will be subject to the Birmingham Corporation Superannuation Scheme and to the candidate passing a medical examination, and will be subject to three months' notice on either side.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by her.

Applications, endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, to be made on a form obtainable from the Medical Officer of Health, Council House, Birmingham, 3, and returned to him on or before August 14th, 1937.

Selected candidates will be interviewed at the Council House on August 25th, 1937.

Further particulars may be obtained from the Secretary, Royal Liverpool Children's Hospital, Myrtle Street, Liverpool, to whom applications should be sent, with copies of recent testimonials, on or before Monday, August 16th, 1937.

THE PRINCE OF WALES'S HOSPITAL, PLYMOUTH.
Incorporating South Devon and East Cornwall Hospital, Greenbank Road; Royal Albert Hospital, Devonport; Central Hospital, Lockyer Street.

Applicants are invited for the following posts on the Honorary Medical and Surgical Staff:

(1) HONORARY AURAL SURGEON. Candidates must be masters of surgery of the United Kingdom, or Fellows of the Royal College of Surgeons of England, or must hold the special diploma in Oto-rhino-laryngology.

(2) HONORARY MEDICAL REGISTRAR. Candidates must be members of the Royal College of Physicians of London or Edinburgh, or M.D. of a University in the United Kingdom.

Applicants must send twelve copies of their application and testimonials to the undersigned by August 21, 1937. Canvassing disqualifies.

Greenbank Road, Plymouth. July 31st, 1937.
ARTHUR R. CASH,
Gen. Supt. and Secretary.

THE PRINCE OF WALES'S HOSPITAL, GREENBANK ROAD, PLYMOUTH.
(Formerly South Devon and East Cornwall Hospital.) (264 Beds.)

Applications are invited for the two vacant posts of HOUSE SURGEON and RESIDENT ANAESTHETIST AND HOUSE SURGEON TO SPECIAL DEPARTMENTS. Salary £120 per annum, with board, residence and laundry.

Appointments are tenable for six months, and are subject to renewal. Duties to commence immediately.

The Hospital is officially recognised for the surgical practice required before admission to the Final Fellowship Examinations of the Royal College of Surgeons of England.

Applicants must be registered under the Medical Acts. Applications, stating age and qualifications, with copies of three recent testimonials, to reach the undersigned forthwith.

ARTHUR R. CASH,
Gen. Supt. and Secretary.

COVENTRY AND WARWICKSHIRE HOSPITAL.

There being a vacancy on the staff for an HONORARY ANAESTHETIST, applications are invited for the post.

Candidates must be duly qualified Practitioners.

The appointment will be made for one year, subject to reappointment annually.

Candidates shall be resident in the City of Coventry, or within six miles radius thereof, or shall take up their residence within that radius within six months from the date of appointment.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Applications, with original testimonials and registration certificates, must reach the undersigned on or before August 14th.

Candidates will in due course receive notice of their eligibility or otherwise from the Secretary, and after receipt of such notice eligible candidates are at liberty to send through the post printed copies of their application and testimonials, to the Members of the Board of Management of the Hospital, a list of whose names and addresses will be furnished by the Secretary. No such applications or copies of testimonials shall be sent until receipt of such notification from the Secretary.

By Order of the Committee,
(Miss) R. HOOPER,
Secretary.

THE YORKSHIRE CHILDREN'S ORTHOPAEDIC HOSPITAL,
KIRBYMOORSIDE, YORK. (124 Beds.)

Applications are invited for the position of HOUSE SURGEON (female). Salary £200 per annum, with board, residence and laundry. Previous orthopaedic experience is not necessary, but preference will be given to candidates who have held resident hospital appointments, and who are competent anaesthetists.

The appointment is for one year, and renewable, and may be terminated by three months' notice.

Applications, with copies of not more than three recent testimonials, should be forwarded to me at the above address, to arrive not later than first post on Friday, August 20th, 1937.

P. HANKS,
Secretary.

THE BUCHANAN HOSPITAL, ST. LEONARDS-ON-SEA. (103 Beds.)

APPOINTMENT OF HON. NEUROLOGIST.

Applications are invited from fully qualified Medical Practitioners for the post of Hon. Neurologist to the above Hospital.

The successful candidate will be required to inaugurate and conduct a clinic in the Out-Patients' Department on an approved day, and include in this clinic the treatment of Psychological cases.

Any candidate canvassing any members of the Elective Committee shall be disqualified.

Applications, together with at least three testimonials, should be sent to the undersigned

FRANK HART,
Secretary.

LIVERPOOL MATERNITY HOSPITAL, OXFORD STREET.

HOUSE SURGEON required for the six months commencing October 1st next, salary at the rate of £90 per annum, with board, residence and laundry. Previous experience as House Surgeon essential. Membership of a Medical Defence Society is a condition of appointment.

Applications, stating age, qualifications and experience, together with copies of testimonials, to be sent to the Honorary Secretary of the Medical Board on or before August 27th.

THE STAFFORDSHIRE GENERAL INFIRMARY, STAFFORD (100 Beds).

HOUSE PHYSICIAN AND CASUALTY OFFICER required on September 1st, also HOUSE SURGEON on September 21st. Salary £150 and £200 per annum respectively. Previous experience is desirable. There are two Resident Medical Officers and a well-equipped Clinical Laboratory.

Applications, stating age, with particulars of experience, and accompanied by copies of three recent testimonials, should be sent to me forthwith.

Stafford, July 30th, 1937.
A. E. COLLINS,
Secretary.

GREAT YARMOUTH GENERAL HOSPITAL.
(72 Beds.)

Applications are invited for the post of HOUSE SURGEON (one of two appointments). Duties to commence August 23rd.

Applicant must be male and unmarried. Salary at the rate of £140 per annum, with board, residence and laundry.

Applications, stating age and qualifications, together with copies of three recent testimonials, to be forwarded to the undersigned.

FREDK. L. GATFIELD,
Secretary

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN
(Usually known as the Children's Hospital),
ST. MICHAEL'S HILL, BRISTOL.

Applications are invited for the position of HOUSE SURGEON, to take duty from September 1st. Salary £125 per annum, with board, rooms, attendance and laundry.

Applicants should state age, qualifications, experience, and send testimonials, to the undersigned on or before August 14th.

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.
No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. BUCKS.—Old-established PRACTICE. Gross cash receipts stated to be over £2,000 p.a. Panel of about 1,550 patients. Fees 3,- to 5/-, with visits from 3/6 to 10/6. The Practice is at present run by two partners, and there is stated to be good scope for two friends working together.
2. YORKS.—LARGE TOWN.—Well-established better working-class PRACTICE. Receipts for last 12 months about £1,176 with Panel of 1,150 patients approximately. Fees, minimum 2/6 with visits from 3/6 to 7/6. Freehold house for disposal at £900 containing 3 bedrooms, 2 living rooms, surgery, waiting room, etc. Vendor wishes to specialise.
3. SURREY.—PLEASANT TOWN.—PRACTICE produced for past 12 months about £1,250 with a Panel of 800 patients. Fees 3/6 upwards, with visits from 5/- upwards. Midwifery 3 to 10 gns., about 15 cases per annum. Vendor has to give up owing to ill-health. Premium £2,000.
4. EASTERN COUNTY AND MARKET TOWN.—HALF-SHARE PARTNERSHIP in Practice established some 100 years, owing to retiral of junior partner. Average cash receipts over £2,400 p.a., of which over £700 comes from Panel and P.A.C. Suitable house available on rental. Ingoing partner should not be more than 30, preferably have a degree and some hospital experience.
5. ASSISTANTSHIP—with a view to a PARTNERSHIP SHARE to produce about £1,100 p.a., in a well-established Practice. Ingoing man must be young, have had considerable hospital experience, and preferably held an Ophthalmic H.S. He should be married or engaged, and a Protestant. Will applicants please give fully details of experience, etc.
6. DEVON, SOUTH COAST.—A well-established good-class entirely private PRACTICE producing for the past 12 months about £1,000. Panel could be had if desired. Fees 2/6, 3/6, 5,- and 7/6, with a few visits up to 21/-. Non-dispensing. Suitable house containing consulting room, 2 reception rooms, 6 bedrooms, for sale. Freehold £1,400. Partnership introduction. Would be suitable for ex-I.M.S. or similar.
7. NORFOLK AND SUFFOLK BORDERS.—A SHARE to produce about £1,100 p.a., is offered in an old-established Practice with considerable scope for increase. Receipts approximately £3,300 with a Panel of some 1,400 patients. Expenses are very low and there is likely to be a choice of houses.
8. DEVELOPING NORTHERN SUBURB.—A 3.8TH SHARE is offered in a well-established and growing Practice. Receipts for 12 months to 1/4/37 amounted to about £5,200, including about £80 from appointments and a Panel of some 5,300 patients. There is a choice of houses available.
9. LANCS.—SUBURB OF LARGE TOWN.—PRACTICE established for 10 years—gross cash receipts for year ended 31/3/37 amounted to about £800, with an increasing Panel of some 470 patients. Fees 2,6 and 3,6., with visits 3/6 and 5/-. Suitable house with good accommodation and separate surgery available on lease at £60 p.a. Premium £1,100, plus good debts, drugs and surgery equipment at valuation. Vendor giving up owing to ill-health.
10. SUFFOLK.—Within easy reach of sea and good towns. Old-established PRACTICE producing about £1,200 p.a. for disposal owing to ill-health. Panel of 700 patients. Nearest opposition 4 miles. Lovely Georgian house, with 2 reception and 4 bedrooms, dressing room and 2 attics. Professional accommodation with separate entrance. For sale £1,600 freehold, or might be rented for a short time. Premium £1,750 or near offer.
11. WEST COAST.—Well-established PRACTICE producing about £1,900 p.a., including Panel of 1,450 patients which gives £820 p.a. and one or two small appointments. Visits 3/6 to 12/6. Consultations 3,6, medicine extra. There is a Cottage Hospital, purchaser would get on the staff. There is stated to be scope for surgery. Suitable house on rental at £50 p.a., with rates of £26 p.a. Accommodation is ample, and consists of waiting and consulting room, dispensary with separate entrance, 2 reception, 7 bedrooms and billiard room, half-acre of garden and garage for 2 cars. Premium 1½ years' purchase.
12. WIMBLEDON.—Old-established PRACTICE for disposal. Gross income about £1,000 p.a., with Panel of 350 patients. There is also a possibility that the purchaser will obtain a hospital appointment worth about £120 p.a. House can be rented on lease or purchased.
13. LONDON, E.2.—Lock-up PRACTICE established 80 years for disposal. Income about £500-£900 p.a., with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available consisting of consulting room, dispensary, waiting room, the remainder being sub-let for £280 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £150 fittings, fixtures, drugs, etc.
14. CENTRAL LONDON.—Long-established PRACTICE for disposal owing to ill-health. Income about £2,300 p.a. Panel of over 3,100 patients. There is also an appointment producing £160 p.a., which is not included in above receipts, but which might be transferable. Suitable accommodation available.
15. CITY PRACTICE.—Lock-up, hours 10-1 and 5.30-6.30, producing about £1,000 p.a., including £200 from Panel and appointments. Suitable accommodation available.
16. [illegible]
17. [illegible]

Small garden and garage for 3 cars. Freehold £1,350. Premium 2 years' purchase.

18. ESSEX COAST TOWN.—A ONE-THIRD SHARE is offered to a physician in an old-established Practice producing about £7,200 p.a. Panel produces about £900 p.a. Consultations 3,6 to 7,6. Visits 5/- to 21/-. There will probably be a choice of houses. Ingoing partner should be aged 35 or over and must have a good hospital experience. He should hold the M.D. or M.R.C.P.
19. SURGICAL OPENING.—WITHIN 50 MILES OF LONDON.—A £1,000 share is offered to a FIFTH PARTNER in an old-established Practice. The patients comprise all classes and there is little visiting done under 10/6. Ingoing partner would do all surgery, but must be prepared to do ordinary G.P. as well. Choice of houses. Applicants must be [illegible] degree and must have their English Fellowship. Premium 2 years purchase.
20. NORTH LONDON.—PRACTICE producing £750 p.a. [illegible] from Panel and £135 from one appointment. Fees 2/6 to 5/-. Suitable accommodation available, 2 consulting [illegible] and dispensary with separate entrances—2 reception [illegible] Nett outgoings approximately £107 p.a. From [illegible]
21. LONDON, S.W.—Old-established PRACTICE producing [illegible] panel of 1,266 patients for disposal. Appointments and [illegible] about £85 p.a. House available consists of [illegible] reception room and 3 bedrooms and maid's room [illegible] might be rented. Premium £3,000.
22. NORTH-WEST COAST.—SEASIDE TOWN.—[illegible] PRACTICE FOR A PHYSICIAN.—Established over [illegible] to come to London) 4 years ago. Receipts for [illegible] Minimum fee 2 gns. Suitable rooms available [illegible] Purchaser can choose his own residence and [illegible] M.R.C.P. Premium 1½ years' purchase on actual [illegible]
23. HAMPSHIRE.—COUNTRY PRACTICE.—[illegible] PRACTICE held by vendor for past 7 years. Gross cash receipts [illegible] £740 p.a. Panel of 472. Appointments worth about [illegible] upwards. Pleasant house containing 2 reception, 5 [illegible] sional accommodation. Good garden and garage. Rent [illegible]
24. LONDON, SOUTH-EAST.—Middle-class PRACTICE [illegible] 30 years, averaging over £700 p.a. Panel of 576 and one appointment worth £25 p.a. Roomy house with good garden and garage. Lease [illegible]
25. OUTLYING EASTERN SUBURB.—PRACTICE established over 40 years and averaging about £1,600 p.a., for disposal. Panel of about 2,000 patients. Suitable premises available at a rent of 30/- per week.
26. SUSSEX.—VILLAGE PRACTICE NEAR COAST.—Well-established PRACTICE producing about £600 p.a., and capable of increase, attractively situated within five miles of favourite seaside resort. Very nice house, with ¾ acre of garden, in excellent repair. Price for Practice and house, £3,100 or house might be rented for a short period.
27. LONDON.—WESTERN SUBURB.—Old-established private PRACTICE producing about £1,100 p.a. for disposal. There is stated to be good scope for a young man who will undertake panel and midwifery. Fees 3,6 to 10,6. Small compact house on rental. Premium £1,500.
28. SOUTH-COAST SEAPORT.—Long established PRACTICE for disposal owing to Vendor's retirement. He has held it for the past 39 years. Income last year approximately £573 with a Panel of about 400 patients. Vendor previously held a public appointment producing £450 p.a. [illegible] relinquished owing to age limit. It is considered that [illegible] time to the Practice would increase the receipts. Suitable [illegible] available on rental.
29. EASTERN COUNTIES.—Mixed-class PRACTICE [illegible] district producing for last 12 months over £1,300 p.a. [illegible] house in good position with 2 reception, 4 bedrooms, [illegible] Separate professional accommodation. Modern conveniences [illegible] garage. Price for freehold £1,300. Sport of all kinds and schools within reach.
30. [illegible] WO GOOD TOWNS.—Old-established [illegible] averaging over £1,600 p.a., [illegible] ow expenses. Detached house in own grounds, containing 2 sitting rooms 5 bedrooms, etc. Rent £70 a year. Premium £1,750.
31. LONDON.—NORTH-WEST.—Recently established and steadily developing PRACTICE producing for last 12 months approximately £1,600, and increasing at the rate of about £200 p.a. Suitable house can be rented or flat obtainable. Premium 2 years' purchase.
32. NORTH-EAST COAST.—Old-established PRACTICE producing about £900 p.a., but stated to be capable of considerable increase. Choice of houses. Partnership introduction given, as vendor retiring.
33. MIDLANDS.—FAVOURITE RESIDENTIAL TOWN.—Chiefly better class non-dispensing PRACTICE, producing for last 12 months over £1,600. Panel of 560 and one appointment worth £150 p.a. Fees 3/6 to 21/-. Very nice house with ample accommodation, garden and garage. Freehold for sale. Premium 2 years' purchase.
34. CENTRAL LONDON.—PRACTICE is worked as a "Lock-up" and averages about £1,000 p.a. Fees from 2,6. Suitable accommodation can be obtained. Premium 2 years' purchase.
35. SUSSEX.—ATTRACTIVE DISTRICT NEAR SEA.—PARTNERSHIP.—A ONE-FOURTH SHARE is offered (after preliminary assistantship of 6 to 12 months) in old-established Practice having good scope. Gross cash receipts for last 12 months approximately £3,275. Panel of about 1,300. Appointments worth over £300. Choice of houses on rental for ingoing partner. Premium 2 years' purchase.
36. SUSSEX COAST TOWN.—PRACTICE established 45 years for disposal owing to retirement of Vendor. Present receipts about £600. There is stated to be scope for increase as receipts have fallen owing to Vendor's [illegible] Panel about 650. Large house can be rented at £150, or part [illegible] probably choose own residence.
37. LONDON.—SOUTH-EAST.—Old-established PRACTICE producing about £1,530 p.a., including select panel of 500. Fees from 3/6. Suitable house available with 2 recep., 5 bedrooms, etc. Freehold for sale. Premium 2 years' purchase.
38. RIVERSIDE TOWN.—Well-established mixed practice PRACTICE producing for last 12 months approximately £960. Select panel of 400 to 450 patients. Visits from 5/-. Very nice house in good repair, with ample accommodation. Garden. Garage. Price for freehold £1,000. Premium £1,250.
39. SOUTH CORNWALL.—FAVOURITE COAST TOWN.—Well-established PRACTICE averaging over £1,100 p.a., including selected panel of about 350. Fees from 2/-. Good freehold house for sale or similar is also available. Premium £2,000. Vendor retiring.

WANTED TO PURCHASE.—PRACTICE OR PARTNERSHIP producing £500 p.a. upwards, and situated within 2 miles of Highgate.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

The art of keeping cool

The relative adaptability of the human body roughly measures the difference between physiological efficiency and inefficiency. The range of climatic variation in these islands is considerable; and it is important, in the interests both of comfort and of health, that the power of bodily adjustment shall be kept actively maintained. Very much may be done by sensible modifications of dress, of exercise and of diet, according to seasonal demands; but unless the blood-stream is kept reasonably free from waste and potentially toxic products, these measures are likely to prove ineffective. Intestinal stagnation is very common during the hot weather, and often leads to a general slowing down of the flow of katabolic products from the tissues. Elimination is facilitated by the taking of a morning glass of ENO'S "Fruit Salt." This pleasant effervescent saline, taken each morning through the summer months, induces a feeling of freshness, animation and agreeable coolness throughout the day.

ENO'S "Fruit Salt" is carefully prepared from fruit acids in combination with alkalis. It is free from all trace of sugar or artificial flavouring matter, as well as from nauseous mineral purgative salts, such as the sulphates of sodium and magnesium, etc., etc.

ENO'S 'FRUIT SALT'

The words 'Eno' and "Fruit Salt" are Registered Trade Marks.

IMPORTANT DETAILS

collectively result in the exceptional efficiency of

SALT'S PATENT COLOSTOMY BELT

This Belt is an outstanding example of the vital importance of details in the construction of a Surgical Appliance. The photographs reproduced on the right show the various component parts of Salt's patent Colostomy Belt . . . each feature having been evolved after much study and experiment . . . all of them collectively resulting in a Belt which definitely secures for patients a degree of comfort and freedom from embarrassment which is certainly most welcome. Further information and Measure/Order forms for this Belt will be found in Salt's Corset and Belt Book. Practitioners are invited to write for this useful Book.

THE "DOCTORS' SHIRT" *which has detachable sleeves!*

Here is a most useful shirt which for many years we have supplied to the medical profession. With detachable sleeves just above the elbow, it fastens with four small buttons which are adjusted with a minimum of trouble. The "Doctors' Shirt" possesses also these additional points of interest.

1. It keeps the cuffs smooth instead of being creased up by the process of rolling.

2. There is no fear of them coming down at an inopportune moment.

3. There is no muster of material about the biceps to interfere with the action of the arm.

The "Doctors' Shirt" is made in white poplin 10/6, Collars 1/3 extra. Extra half sleeves sold separately. Also other fabrics striped or plain. For prices, patterns, and self-measurement form send to Dept. B.M.J.

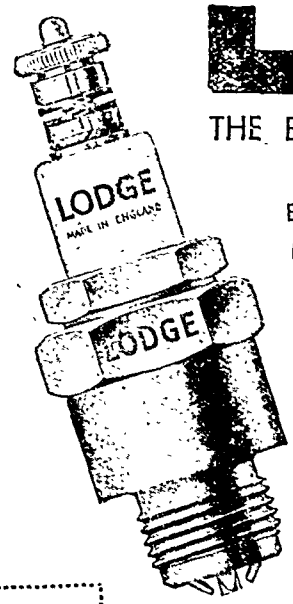
Eusterman and Balfour on the Stomach and Duodenum

"A volume which embodies the unique experience of a group of experts working in an unrivalled organisation" says the Edinburgh Medical Journal.

"It would be difficult to write too highly of this work on the stomach and duodenum, which has been produced by the Heads of the Sections of Medicine and Surgery of the Mayo Clinic, Drs Eusterman and Balfour, in collaboration with other members of the staff of the Clinic. The standard of authority and experience may be gauged at once from the fact that the section on applied physiology of the stomach and duodenum is written by Dr. Alvarez, that on experimental production of ulcer is by Dr. Mann and that on surgical pathology by Dr. McCarthy. In short, we have here a volume which embodies the unique experience of a group of experts working in an unrivalled organisation. ***Needless to say the book is, and will long remain, one of the best books of reference on the subject.*** *It is unnecessary to do more than indicate some of the contents. Besides the sections mentioned above there are chapters on dyspepsia, test meals, symptomatology and roentgenological diagnosis; peptic ulcer in stomach and duodenum is dealt with very completely and malignant disease receives due consideration. One special feature is the clear description of the technique of surgical operations; an appendix contains diet-sheets for pre- and post-operative treatment. The illustrations are numerous and excellent. There is an adequate and well-selected bibliography. We heartily welcome this volume and recommend it to all surgeons and physicians who are interested in diseases of the stomach and duodenum."*—EDINBURGH MEDICAL JOURNAL.

By GEORGE B. EUSTERMAN, M.D., F.A.C.P., Head of Section in Division of Medicine; DONALD C. BALFOUR, M.B., M.D. (Tor.), LL.D., F.A.C.S., F.R.A.C.S., Head of Section in Division of Surgery; and MEMBERS OF THE STAFF of The Mayo Clinic and The Mayo Foundation, Rochester, Minn. Octavo of 958 pages, with 571 illustrations on 436 figures. Cloth, 45s. net.



The same Journal says of Levine's Clinical Heart Disease

that it is "a refreshing and interesting book which will appeal to the practitioner to whom it is expressly addressed."

"The author of this clinical handbook is a well-known American cardiologist working at the Harvard Medical School and at the Peter Bent Brigham Hospital, Boston. His monograph is the outcome of this experience and is largely based on personal observations and clinical studies previously published. The result is that Dr. Levine writes with reinforced authority on various circulatory subjects suitably arranged chapter by chapter, but with no ordered sequence, so that each discussion is complete in itself. This proves more successful than might at first be anticipated, for the author is revealed as an able clinician ready and willing to formulate valuable and interesting opinions, differing occasionally from the more orthodox and conservative views often expressed in the formal text-book. As a specialist in an important branch of medicine Dr. Levine has succeeded in casting aside the mantle of obscurantism, and by discarding many of the technicalities and dogmatisms, which have tended to encumber this subject in recent years, he has made a refreshing and interesting book which will appeal to the practitioner to whom it is expressly addressed. This is a notable achievement, ***for few specialists in any branch of study are gifted with the ability to write so simply, lucidly and clearly.*** *There are many excellent chapters, amongst which we found those on thyrotoxic heart disease, on the significance of the systolic murmur, and that devoted to the patient as a surgical or obstetrical risk particularly interesting."*—EDINBURGH MEDICAL JOURNAL.

By SAMUEL A. LEVINE, M.D., F.A.C.P., Assistant Professor of Medicine, Harvard Medical School. Octavo of 450 pages. Cloth, 24s. net.

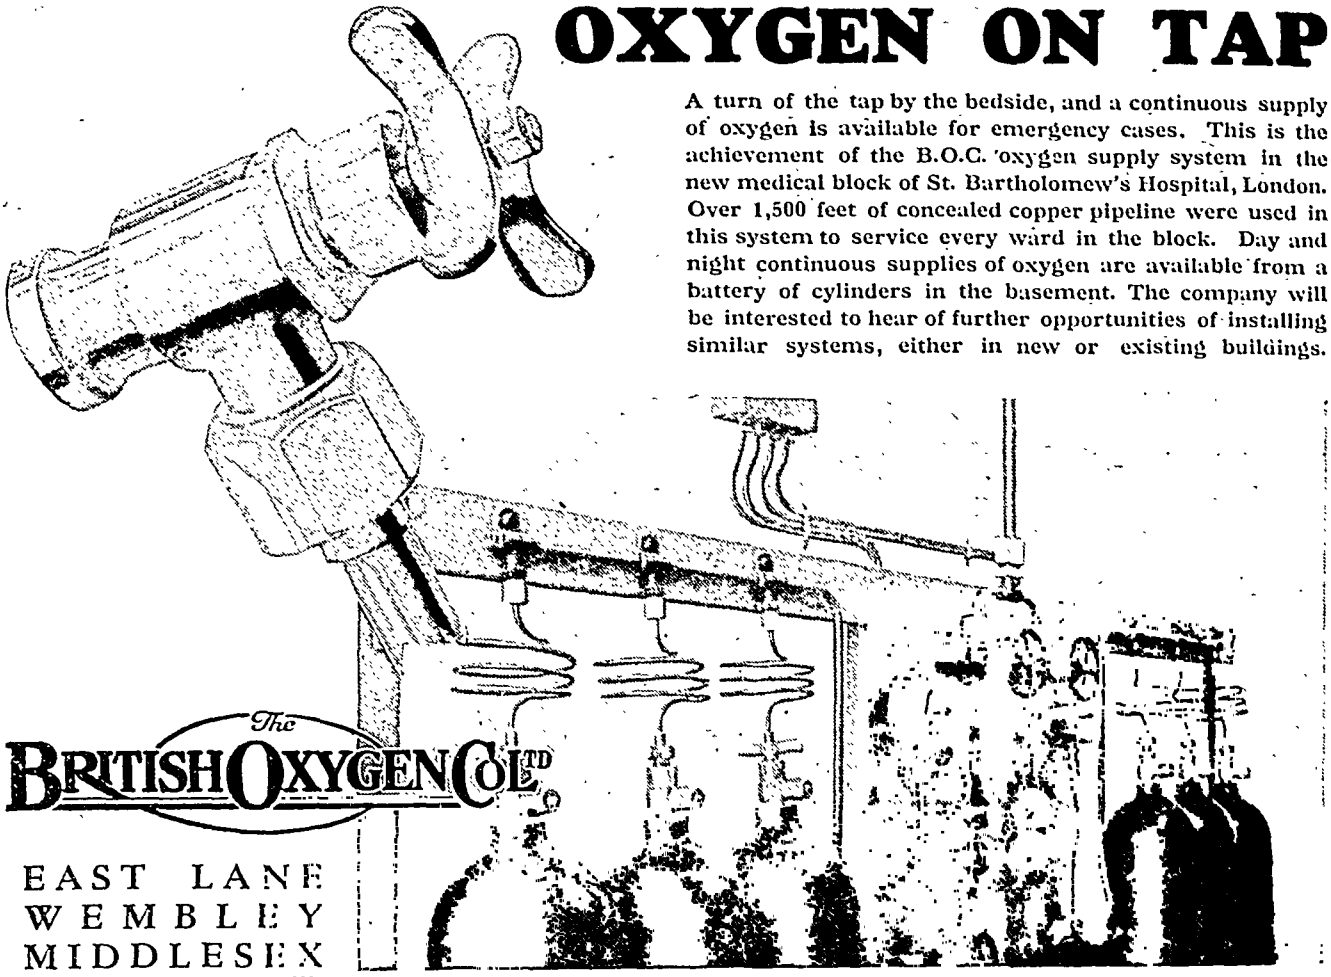
A major operation in progress in the operating theatre of a London Hospital.

THE LESSON OF ANTISEPTICS

LISTER'S discovery that suppuration of wounds was caused by bacterial infection and could be prevented by the use of antiseptics opened the way to the marvels of modern surgery. To-day, it is taken for granted that every operation will be carried out without the introduction of micro-organisms into the blood.

Recognition of the importance of germ-free cleanliness, however, is no longer confined to the operating theatre and surgery; it receives ever-increasing attention from the lay public. Health standards to-day are higher than they have ever been, as a result. Naturally, elaborate precautions against infection are impracticable in everyday life, but fortunately adequate protection is provided by the liberal use of soap and water—provided that the soap is pure and has antiseptic qualities.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for over 70 years. Leading bacteriologists advocate its use for everyday protection against infection, and it has been found that more doctors use Wright's than any other brand of toilet soap. Wright's has substantial antiseptic and antipruritic qualities, and is the only soap to contain 'liquor carbonis detergens' (Wright's), the valuable skin therapeutic used and recommended by the foremost dermatologists. You can use and recommend Wright's Coal Tar Soap with every confidence.

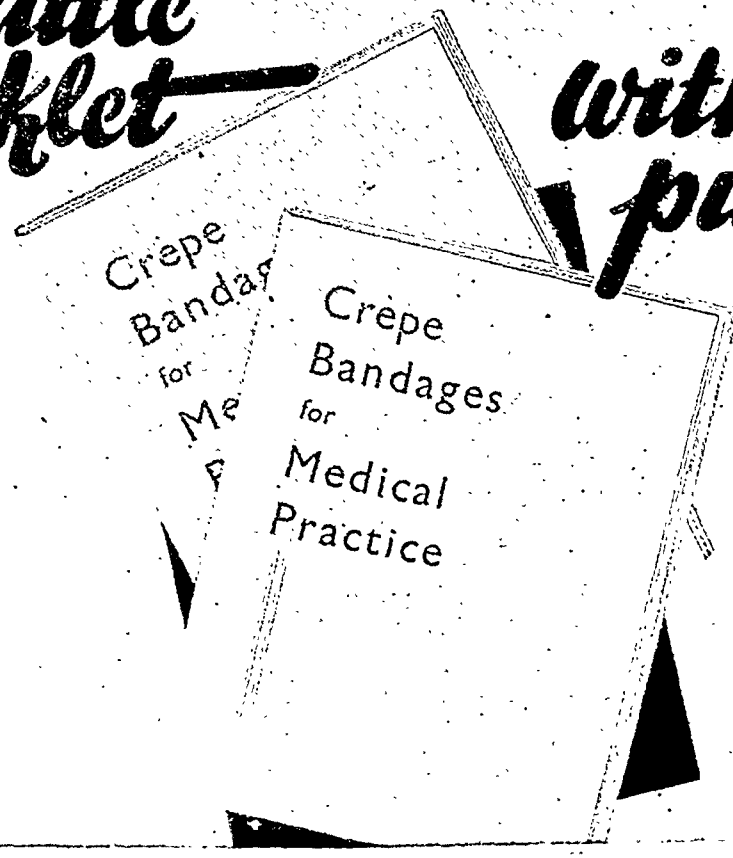


WRIGHT'S COAL TAR SOAP

The Safe Soap

Wright, Layman & Umney Ltd., 44-50 Southwark Street, S.E.1

OXYGEN ON TAP



A turn of the tap by the bedside, and a continuous supply of oxygen is available for emergency cases. This is the achievement of the B.O.C. oxygen supply system in the new medical block of St. Bartholomew's Hospital, London. Over 1,500 feet of concealed copper pipeline were used in this system to service every ward in the block. Day and night continuous supplies of oxygen are available from a battery of cylinders in the basement. The company will be interested to hear of further opportunities of installing similar systems, either in new or existing buildings.

A Spencer Supporting Corset shown open, revealing inner belt and its tapes, which emerge outside the corset. The degree of uplift may be changed instantly from the outside, providing snug adjustment at lower part of abdomen and freedom at upper part, as required. Note that the "pull" of the abdominal support is placed on the pelvic girdle.

Shews ptosis of stomach and colon.

Shews how the Spencer Supporting Corset assists the condition by supporting the organs involved in as near normal position as possible.

For VISCEROPTOSIS

A Spencer Support relieves the condition by providing "uplift" and improving posture

SPENCER SUPPORTS are distinguished from ordinary supports in that every section, every line is individually designed, cut and made to meet the particular needs of the one patient who is to wear it. Hence, they fit so exactly they do not "ride-up" on the figure and are perfectly comfortable. All Spencers are light in weight, flexible, easily laundered, and guaranteed NEVER to lose their shape. (Any support that loses its shape loses its effectiveness. Spencers are, to our knowledge, the only garments that carry a guarantee to hold their shape until worn out.) They are well liked by patients in all walks of life because they are economical and provide graceful carriage.

Spencer individual designing makes possible these three essentials: the weight of support is always placed on the pelvic girdle—NEVER on the spine at, or above, the lumbar region; the abdominal section, being shaped to the individual needs of the patient, provides specific uplift, without compression, and each Spencer is especially designed to improve the posture of the patient.

Spencer Supports are individually designed for: Breast Conditions, Hernia, Sacro-iliac and Lumbosacral Strain, Enteroptosis and Intestinal Stasis, Movable Kidney, Pregnancy and Post-partum Support.

A scientifically trained Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

Spencer Supports and Corsets are never sold in shops.

The advantages of the Curtis Abdominal Support No. 1 lie in its *anterior - posterior* pressure. By this method the lower abdomen is effectively supported while the hips are given complete freedom of movement. This, combined with its scientific design and extreme lightness in weight, makes the Curtis Abdominal Support No. 1 the most efficient and comfortable on the market.

VERONIGEN

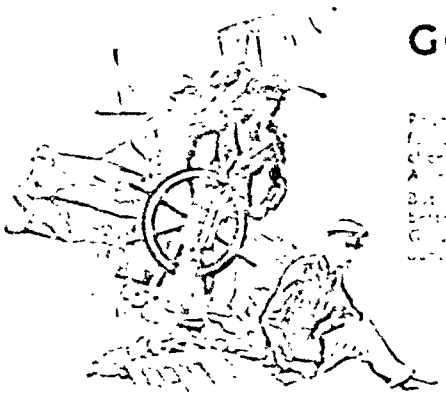
A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor is cumulative in action, and in ordinary cases of insomnia, one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anaesthesia is induced, and as a result much less of the anaesthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used when the heart is weak. Where sleeplessness is a concomitant of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETOSALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

In 5, 10, 22, 40, and 90-oz. Bottles.

Introduced and Prepared only by **C. J. HEWLETT & SON, LTD.** Wholesale and Export Druggists.

35-42, CHARLOTTE STREET, & 83-85, CURTAIN ROAD, LONDON, E.C.2.



SHOP WINDOWS

Who is not tempted to glance at the goods displayed in the shop windows which brighten the streets of every town? The subtle attraction of articles thus brought to notice cannot be explained by any immediate need to purchase. Indeed, the majority of the contents of shop windows have no immediate appeal. They are seen and a mental note is made which may well prove useful later on.

So it is with the advertisements in the *British Medical Journal*. Sometimes, it is true, the reader searches these pages to find a particular preparation or appliance for use in the treatment of a specific case. More often the advertised products are noticed and remembered pending their being required at some future time.

In this way an up-to-date knowledge of proprietary aids to medical practice can be maintained without expense and with very little expenditure of time.

Two helpful suggestions: Pages may be cut out and filed for future reference, and it is always worth while to mention the B.M.J. when writing to advertisers.

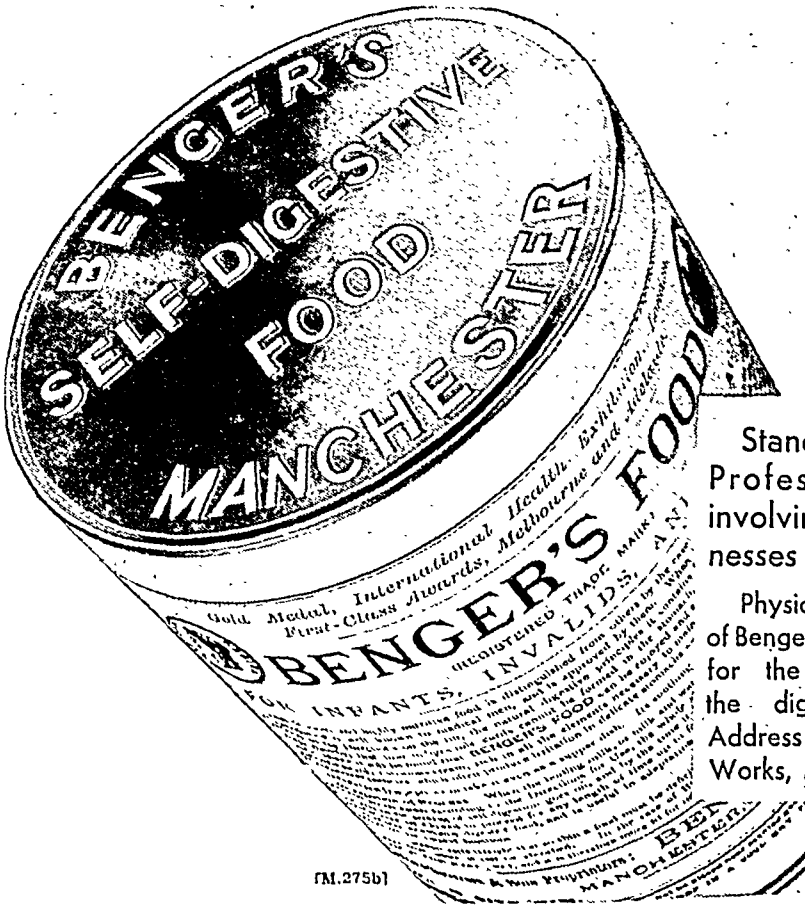
ECZEMA

Relief and cure with Peat ointment.

Because eczema generally brings pain and itching, any local dressing should attempt soothing as well as healing. And this is the great virtue of Sphagnol peat ointment — that from its first touch, it gives coolness and comfort to tender skin.



Many doctors find Sphagnol so successful that they are prompted to write about it. Here is an extract from one of the letters we have received:

"Thank you for the ointment. I have tried it on an incipient case of local eczematous trouble and found it to give great relief and to arrest the manifestation." Signed (Dr.) R. L.

Test Sphagnol personally. On receipt of a postcard we shall be pleased to send you a sufficient supply.

VICHY-CÉLESTINS

THE WORLD-RENOWNED-

NATURAL MINERAL WATER

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Célestins,** by its slightly stimulating action, clears out the stomach, and thus avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

NATURAL VICHY SALT for Drinking and Baths.

VICHY DIGESTIVE PASTILLES prepared with Natural Vichy Salt.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

MANDELIX

(ELIXIR OF AMMONIUM MANDELATE B.D.H.)

In Urinary Tract Infections

The administration of Mandelix, a palatable elixir of ammonium mandelate, in urinary tract infections is followed, in the majority of cases—even in those having a chronic infection—by most satisfactory results: indeed, as stated in a report on its clinical use '. . . a sterile urine was effected in a week or less, though all had a chronic infection' (Lancet, April 4th, 1936, p.769).

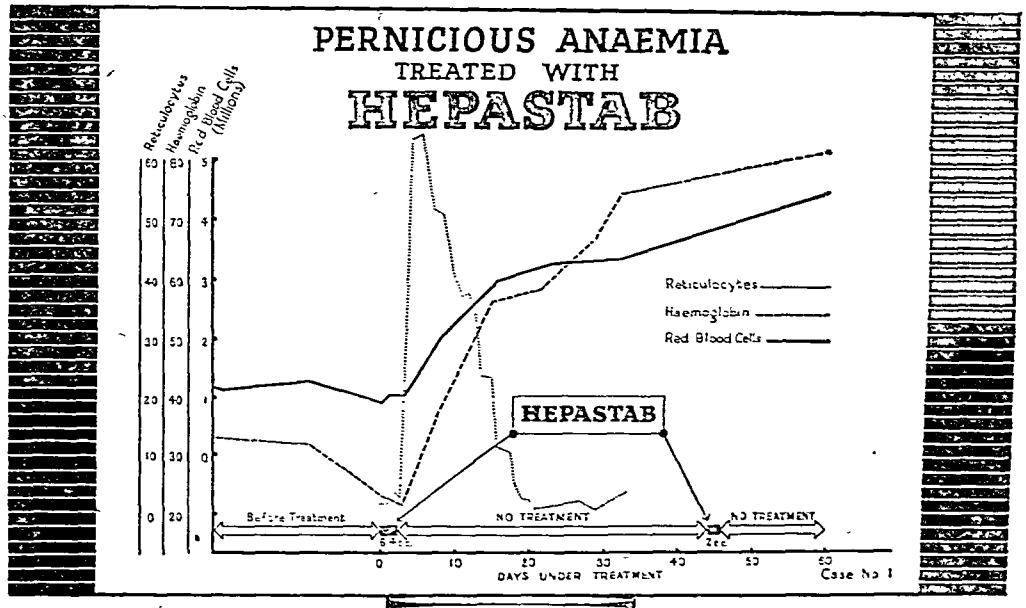
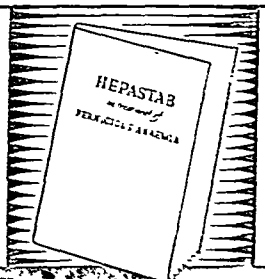
FOR THE TREATMENT OF PERNICIOUS ANAEMIA



TRADE MARK

HEPASTAB



BRAND

Intramuscular Liver Extract.

"It is universally agreed that parenteral treatment of pernicious anæmia is very efficient and cheap, and enables definite therapy to be given to the patient whatever the clinical condition. This is the only satisfactory method of treatment when the anæmia is associated with impairment of gastro-intestinal absorption. The responses are dramatic and the subsequent maintenance doses are such that only occasional small injections need be given at intervals of two to six weeks."—(*Pract.*, *1936*,*137*,*453*)

Every batch of Hepastab is subjected to clinical trial under rigidly controlled conditions.
Supplied in 2 c.c. and 4 c.c. ampoules.

Copies of our booklet entitled "Hepastab in the Treatment of Pernicious Anæmia" will be sent on request.

BOOTS PURE DRUG CO. LTD NOTTINGHAM, ENGLAND

Purity · Activity · Stability

INSULIN 'A.B.'

Insulin 'A.B. was the first British insulin offered commercially to the medical profession. Its manufacture on an industrial scale was the direct result of research carried out by the joint manufacturers in their physiological and chemical laboratories; its supremacy has been fully maintained by the persistent work of the research staff engaged in its production.

Insulin 'A.B.' has a world-wide reputation for its strictly safeguarded sterility, its carefully standardised strength, its freedom from toxic reactions and its stability in hot climates.

Supplied in three strengths.

20 units per c.c.

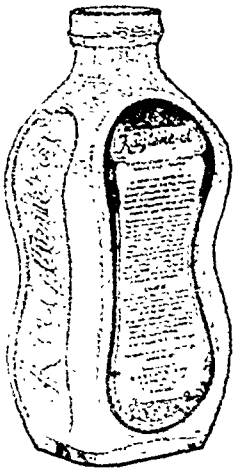
Practical applications of the



KAYLENE-OL

KAYLENE TERRA SIG. ILLATA BRAND

Treatment

CHRONIC COLITIS

(Simple Mucous, Muco-Membranous, Post-Dysenteric).

(Kaylene Brand of Colloidal Kaolin with highly viscous liquid paraffin)

Alternating intervals of constipation and diarrhoea often occur in cases of colitis. Kaylene-ol is applicable in either phase. Its soothing and adsorptive actions combat the irritative diarrhoea, and its softening and lubricating actions counteract constipation during the intervals.

DOSE—KAYLENE-OL: 1 or 2 dessertspoonsful three times a day, half hour before meals, or in mild cases half hour before breakfast and at bedtime.

Kaylene-ol c Phenolphthalein (0.5 per cent.) is taken when constipation is particularly troublesome. Dosage as for Kaylene-ol.

Samples and Literature from the sole manufacturers:

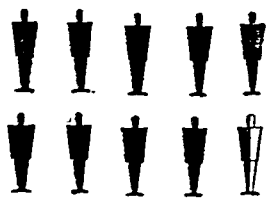
Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the proto-carbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids



You are cordially invited to apply for samples for clinical test.
The Iron 'Jelloid' Co. Ltd., King George's Avenue, Watford, Herts.

BRAN

as effective as strong laxatives . . . *without the consequence*

7½D Per Packet

98% cases of CONSTIPATION yield to the BRAN remedy—

In laboratory tests, Bran has proved a definite remedy in 98 cases out of 100. The failures were all due to the patients' inability to accommodate bulk in fruit, vegetables, or Bran.

Most modern diets being deficient in bulk, the addition of a laxative agent becomes a necessity. Kellogg's ALL-BRAN supplies this deficiency and ensures regular elimination. ALL-BRAN needs no cooking. It is served with milk, cream or fruit and, in combination with moisture, forms a sponge-like mass in the body. This gently exercises the intestines and stimulates natural action.

Some patients prefer Kellogg's ALL-BRAN cooked in biscuits, cakes, omelettes, etc. It is rich in easily assimilable Vitamin B and iron.

Kellogg's ALL-BRAN is effective in all constipation cases except where a hyper-sensitive alimentary tract makes its use inadvisable.

Full-sized sample packet free on request.

THE THERAPEUTIC VALUE OF THE BANANA

II. Gram-Positive Results

B. S. Kahn states that fructose is an exceedingly favourable medium for the growth of Gram-positive intestinal bacteria. He reports that infants fed on a milk mixture containing 5 per cent. of banana powder showed a conversion of the intestinal flora from an almost complete Gram-negative to an almost complete Gram-positive state.

If, as appears possible, this is due to fructose, it emphasises the use of the banana as an article of diet during treatment, but only of course when fully ripe, for it is then that the fructose percentage is at its highest. In the successful use of bananas in the diet of diabetics, the improvement of the faecal flora has been assigned as this cause.

N.B. In the fully ripe banana the starch content is reduced to about 3 per cent., having been changed into soluble sugars. A banana is ripe when all green has disappeared from the skin and brown spots have formed upon the yellow surface.

Cystopurin

The ideal biliary antiseptic

1 Produces no irritation or toxic effects.

2 Is readily absorbed.

3 Is active in either an acid or alkaline medium.

4 Renders the bile bactericidal and sterilises infected bile and the biliary passage.

5 Acts on causative organisms which may reach the biliary system through the systemic circulation and the alimentary tract.

6 Acts as a prophylactic.

7 Promotes biliary drainage.

8 Is perfectly safe, even in large doses.

CHOLECYSTITIS

From information received :—

"I wish to state that the patient with cholecystitis to whom I administered Cystopurin has recovered."

"Cystopurin worked well in cure of cholecystitis and cleared up all symptoms and tenderness. There is no doubt it is good and far easier to take and absorb than any similar preparation."

"Oral administration of Cystopurin was shown to be preferable to —— and within 15 days of the commencement of daily treatment, the organisms entirely disappeared. ——, administered for a similar period, whilst freeing the urinary system of organisms, failed to influence the infection of the gall bladder and bile, which remained positive."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

Samples and literature available on request to

GENATOSAN LIMITED, Loughborough, Leicestershire.

Fiat tablet	0.35 ,,

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of TAXOL, revert to normal and regular peristalsis.

"CERABAN" ADHESIVE SELF-SUPPORTING BANDAGE

The Supplementary or Alternative Treatment to Self-Adhesive Elastic Bandages for

SPRAINS, DISLOCATIONS, CONTUSIONS, SWELLINGS, VARICOSE VEINS, VARICOSE ULCERS, ETC.

Its use eliminates the risk of Dermatitis which so frequently arises from the application of Self-adhesive Bandages.

"CERABAN," whilst free from rubber, possesses elastic properties and when carefully applied to the limb gives substantial support. It is porous, adhesive, and non-irritating, will not chafe and permits of complete respiration of the skin.

In the treatment of Varicose Ulcers the use of "Ceraban" Bandage eliminates the risk of Dermatitis which occasionally occurs through the application of self-adhesive Elastic Bandages. In the less severe of such cases a distinguished authority writing in the *Lancet, page 580, Sept. 7th, 1935, issue* recommends the use of "Ceraban" Bandage cut in strips as a first and protective dressing prior to covering with self-adhesive Elastic Bandage and in the more serious cases the complete replacement by "Ceraban." It is waterproof, antiseptic, and being spread on an extensible material readily conforms to the shape of the limb and therefore will not slip.

INDIVIDUAL VARIATION IN RESPONSE TO DRUGS*

BY

A. J. CLARK, M.D., F.R.C.P., F.R.S.

Professor of Pharmacology, University of Edinburgh

Every practitioner is familiar with the wide variation shown by patients in their response to drugs. Therapeutic success is indeed dependent on the adjustment of standard methods and doses to the needs and peculiarities of the individual patient. Such work makes special demands on clinical skill and experience, and here the general practitioner has a special advantage on account of his knowledge of the patient's peculiarities. It is sometimes suggested that medical practice is degenerating into an automatic process whereby diagnosis is supplied by a laboratory and the appropriate remedy by a therapeutic index. The individual variation of patients will, however, always constitute a factor limiting such tendencies, and is a sure safeguard against the replacement of practitioners of medicine by automatic machines.

The actual range of individual variation tends to be ignored because most therapeutic methods are such that the amount of drug given can be adjusted to the individual need. If the same dose of a drug is given to every individual in a large population then the extent of individual variation is at once revealed. Therapeutic methods of this type, however, are comparatively rare.

The usual method adopted in the administration of powerful drugs is to start with a small dose and to observe the effects produced on the patient before working up to a full dose. The administration of a volatile anaesthetic is an example of the manner in which it is usual to correct individual variation, since the anaesthetist concentrates his attention on each patient, and by suitable adjustment of the dosage secures a uniform response. Most well-established clinical methods of drug administration are of this type, and hence the range of individual variation is masked, and indeed is in danger of being forgotten. This is evidenced by the fact that from time to time therapeutic methods are recommended which involve giving patients a full dose of some potent drug without providing any opportunity for first determining their individual response to it. In most cases such a risk is unnecessary, but in some it is very desirable to produce a full therapeutic action as quickly as possible, and therefore to know the probable limits of human variation. The chief problem is to ascertain what ratio between the average lethal dose and the therapeutic dose represents a reasonable margin of safety in the use of a drug. The extent of the margin actually desirable is a matter of opinion, but it will be generally agreed that if a therapeutic measure involves the chance of producing a serious toxic effect even in one case in 1,000, it must be considered dangerous. This chance will therefore be taken as representing the limit of justifiable risks.

The determination of the incidence of severe toxic effects is obviously a problem which the clinician is glad to leave to the laboratory worker, and hence no apology is needed for the discussion of evidence provided by animal experiments. In order to measure directly the occurrence of occasional toxic actions it is necessary to use very large populations; considerations of cost preclude the employment of any but small animals, and therefore the discussion of individual variation must be based chiefly on experiments made on large numbers of rats and mice. It is obvious that there is a very wide difference between mice and men; but for the reasons mentioned the evidence available is limited, and it is necessary to make as much use as possible of the existing material.

Individual Variation in Animal Populations

The lethal dose of a drug is a primary pharmacological constant, and usually is one of the first characteristics to be determined. Until about twenty years ago the method employed was to give varying doses to a dozen or a few dozen animals, and to term the smallest dose which produced death the minimum lethal dose. Such doses were stated as mg./kg., and thus correction was made for variations in body weight. The introduction of the biological standardization of drugs necessitated increased accuracy in such methods, and as soon as systematic investigations were made it was found that animals showed a considerable individual variation in their responses to drugs, and that consequently the methods that had been in use for a century were inherently inaccurate.

The outstanding results of research of this type are as follows. All populations of animals show individual variation to all drugs. The extent of the scatter of the individual variation depends both on the nature of the population and on the drug. The scatter can be reduced by making the population as uniform as possible—for instance, by the use of inbred animals instead of stock animals, and by the use of animals similar in sex, body weight, and age. The nature of the diet is another important factor—for example, vitamin deficiency increases the susceptibility of animals to many drugs (Wien, 1936). Finally, it is essential to use only animals in good health. Even when all of these precautions are taken animals still show a wide variation in their response to drugs. For example, Poe, Suchy, and Witt (1936) measured the lethal dose of strychnine salts for rats. They used about 4000

* Read in opening a discussion in the Section of Pharmacology and Therapeutics, including Anaesthetics, at the Annual Meeting of the British Medical Association, Belfast, 1937.

animals, and therefore their results are statistically significant. In the case of adult male rats the average or mean lethal dose (50 per cent. mortality) was 2.25 mg./kg., but 4 per cent. were killed by 1.5 mg./kg., and a similar number survived 3.5 mg./kg. They found, moreover, that the mean lethal dose for adult females was 60 per cent. of that for males, whilst the mean lethal dose for young animals was about 70 per cent. that for adult animals. In the case, therefore, of adult animals of mixed sexes 4 per cent. were killed by about one-fourth the dose which 4 per cent. survived. In view of this result it is not surprising to note that previous workers who had estimated the minimum lethal dose for strychnine on rats by the old method of using one or two dozen animals had obtained results varying from 0.7 to 3.4 mg./kg.

The scatter shown in the individual variation of the response to drugs unfortunately differs very widely in the case of different substances. The simplest method of describing the scatter is by measuring the coefficient of variation. The "standard deviation" in the response to a drug is approximately equal to the difference between the doses producing 50 per cent. mortality (mean lethal dose) and that producing 16 per cent. mortality. (For the sake of brevity the mean lethal dose will be termed M.L.D.) The difference between these two doses expressed as the percentage of the M.L.D. is approximately equal to the "coefficient of variation." Examination of characteristic curves which relate dosage and percentage of mortality show that these vary from steep symmetrical sigmoid curves to highly skewed curves approximating in form to a hyperbola. The coefficient of variation in the former case may be as low as 10 per cent., whilst in the latter case it may be as much as 50 per cent. The occurrence of curves of the latter type raises the following difficulty. Our aim is to discover what percentage of the M.L.D. is likely to be safe—that is, to kill less than one animal in 1,000. The determination of this fact by direct experiment would involve the use of at least 10,000 animals for a single drug; but if the shape of the characteristic curve from 10 per cent. to 90 per cent. mortality is established, and the laws of probability can be applied, then it is possible by extrapolation to calculate the chance of a mortality of 1 in 1,000. If a variation is due to a large number of independent factors of similar importance then the distribution follows the "normal curve of error"; and if, for example, 90 per cent. of the M.L.D. kills 16 per cent., then the standard deviation (σ) is $100 - 90 = 10$, and $100 - 3\sigma = 100 - 30 = 70$ per cent. of the M.L.D. will kill about one individual in 1,000.

This simple calculation cannot, however, be applied to highly skewed curves, since it produces the absurd result that a considerable proportion of a population is killed by a dose of less than nothing. It has been shown by Gaddum (1933) that reasonable results can be obtained if characteristic curves are plotted with the dosage on the logarithmic scale. This converts the skewed curves described above into sigmoid curves. In the case already mentioned a 16 per cent. mortality is produced by nine-tenths of the M.L.D., and according to this method of estimation 1 in 1,000 mortality would be produced by $(9/10)^3 = 73$ per cent. of the M.L.D. In this case the two methods of calculation give very similar results, but in a case where 16 per cent. mortality is produced by half the M.L.D. the usual method of calculation results in the absurd conclusion that 3 per cent. mortality is produced when the dose is *nil*, whereas the logarithmic method gives the possible result that 1 in 1,000 mortality is produced by $100 \times (\frac{1}{2})^3 = 12.5$ per cent. of the M.L.D.

The calculation of incidence of effects by plotting the factor causing the effect on a logarithmic scale is not a new suggestion, since its use was recommended and justified in the case of living populations by Galton and MacAlister as long ago as 1879. Table I gives a few typical results obtained with this method of calculation. These results show that although individual variation always occurs, yet, with carefully selected populations of rats, its range in the case of many important drugs is relatively narrow, and that in most of the cases quoted a dose equal to 40 per cent. of the M.L.D. is safe (that is, will not kill more than 1 in 10,000 individuals). The example of dysentery toxin proves, however, that certain poisons are inherently unsafe, since the individual variation is so great that a very small fraction of the mean lethal dose will suffice to kill susceptible individuals.

TABLE I

	Fraction of Mean Dose which should Produce Effect	
	Once in 1,000 Individuals	Once in 10,000 Individuals
Lethal actions:		
Digitalis on frogs	0.5	0.42
Neoarsphenamine on rats	0.56	0.5
Strychnine on rats	0.47	0.4
Thallium on rats	0.47	0.39
Amytal on cats	0.5	0.42
Dysentery toxin on rats	0.036	0.016
Insulin convulsions in mice	0.33	0.25

The drugs that are shown by animal experiments to be possibly safe are obviously of chief interest, and the problem is to estimate what proportion of the mean lethal human dose is safe therapeutically.

Human Lethal Dose

We are at once confronted with the difficulty that the mean lethal human dose is not known for any drug. In the case of a common poison such as strychnine textbooks of toxicology provide the following information. Several deaths have occurred when the dose taken was probably not more than 1/2 grain. Deaths from 1/4 grain have been reported, but the evidence is less certain. Recovery after 2 grains is fairly well established, and recovery after 3 or 4 grains has been reported. Obviously it is nearly always difficult, after the occurrence of a fatal case of poisoning, to obtain reliable information as to what dose has been taken. Furthermore, in the case of recovery it is always uncertain how much of the drug has been removed unabsorbed from the stomach. It is worth noting, however, that animal experiments with strychnine proved that there was a fourfold range of dosage between the least resistant and the most resistant 5 per cent. of a population, even when every endeavour had been made to exclude causes of variation. Hence there is no reason to suspect the statement that some adults have been killed with 1/2 grain of strychnine and others have recovered from 2 grains.

The animal experiments are of service in that they provide formal proof of the fact that the minimum lethal dose is a quantity which cannot be measured accurately. It is simply the smallest dose that has been observed to be followed by death, and in the case of any drug the greater the population observed the lower the value is likely to be.

It is therefore preferable in toxicology to describe the usually fatal dose, and to avoid the term minimum lethal dose.

Human Variation to Narcotics

Quantitative evidence regarding the extent of the variation of the response of patients to therapeutic doses of drugs is very scanty. In the case of the narcotics used for pre-anaesthetic medication a certain amount of accurate evidence exists, because drugs such as nembutal, sodium amytal, and evipan are given by slow intravenous injection until a constant response is produced. Such methods provide exceptionally accurate evidence regarding the relation between dosage and the incidence of a constant response in a human population. For example, Paxson (1932) measured the amount of sodium amytal (mg./kg.) needed to produce analgesia in fifty-five women during labour. His results show that 16 per cent. were narcotized by three-fourths of the median narcotic dose. This is a variation like that found for the lethal action of sodium amytal in cats, rabbits, and rats (Swanson and Page, 1927), and for the related compound sodium nembutal given intravenously to dogs and rats (Swanson and Shonle, 1931) and to rats alone (Gage, 1933). Variations of a similar extent were observed in these cases in respect to both the hypnotic and the lethal doses.

Similarly in the case of avertin given per rectum, the figures of Flörcken and Mues (1928) indicate that 50 per cent. of the population is narcotized by 80 per cent. of the dose needed to narcotize 84 per cent. The scatter as regards the proportion of a population of rats anaesthetized by graded doses of avertin (per rectum) is of similar extent (Lendle, 1928; Tunger, 1931; Gage, 1933). These facts permit the calculation of the extremes of response that are likely to be encountered in a population of 1,000. These are shown in Table II.

TABLE II

Ratio of Doses Producing Effect in 16 and 50% of Population (D_{16}/D_{50})	Percentage of Mean Dose (D_{50}) Producing Effect		Ratio *a/b*
	(*a*) In 0.1% Population	(*b*) In 99.9% Population	
0.75	42	237	1/5.6
0.8	51	200	1/3.9
0.9	73	137	1/1.9

Reports regarding the occurrence of exceptional responses to basal narcotics indicate variation within the scale shown in Table II. In the case of avertin Shipway (1936) found that 1,300 out of 1,500 cases were narcotized by doses between 0.09 and 0.1 g./kg., but that three cases (0.2 per cent.) required 0.12 g./kg. This distribution suggests a ratio D_{16}/D_{50} of a little less than 0.9.

In the case of evipan McNelis (1936) noted that in 1,000 cases one man required 4 grammes to produce anaesthesia, and that with one woman 0.9 gramme appeared to be an overdose. This is the type of result to be expected from a D_{16}/D_{50} ratio of 0.8.

These results indicate that the variation in human beings in response to narcotics is very similar to the variation which occurs in animal populations. It would appear that a D_{16}/D_{50} ratio of about 0.8 must be expected, and consequently in a thousand cases it is probable that the most resistant individual will require about four times the dose needed by the least resistant individual. This unavoidable and unpredictable human variation would seem to constitute an important limiting factor in basal narcosis. Those methods in which the dosage can be adjusted to the individual response would appear to be preferable to those in which a standard dose has to be given to all patients. The latter method is satisfactory in the majority of cases, but produces unfortunate results when individuals are encountered who represent the extreme of variation.

Blood Alcohol and Intoxication

The measurement of the concentration of alcohol in the blood seems to be a much more accurate and scientific method than the estimation of the degree of intoxication by clinical examination. It is important to note, however, that although the former method may indicate accurately the amount of alcohol that has been taken, it does not indicate the effect produced on the patient, because there is a wide individual variation in regard to alcohol concentration in the blood and intoxication. This is shown by the reports of Bogen (1927) and of Widmark (1932), which describe in 250 and 562 cases respectively both the blood concentration of alcohol and the result of clinical examination. The results agree in demonstrating that a concentration of alcohol in the blood of 1.2 mg. per 100 c.cm. produces intoxication in 50 per cent. of cases. Bogen's figures show that intoxication was not present in any case in which the alcoholic content was less than 1 mg. per 100 c.cm.; whilst Widmark found none below 0.8 mg. per 100 c.cm., but observed six cases of intoxication in thirty individuals in whom the blood concentration was between 0.8 and 1.0 mg. per 100 c.cm. At the other end of the scale Bogen's figures show one case in thirty-five not intoxicated with 4 to 5 mg. per 100 c.cm., whilst Widmark's figures give one case in twenty-nine not intoxicated by 2.5 mg. per 100 c.cm. The ratio between the alcohol concentration not intoxicating the most resistant individuals and that affecting the least resistant individuals was about fourteen to one in Bogen's series and three to one in Widmark's series.

Examination of the figures shows that they do not follow the ordinary laws of probability, for there appears to be a lower limit of about 0.8 mg. per 100 c.cm., below which intoxication never occurs; whilst a concentration of 1.2 mg. per 100 c.cm. produces intoxication in about 50 per cent. of the population, but the more resistant half of the population reveals a wide scatter.

Animal experiments give a relatively small variation in response to alcohol. For example, Lendle's (1928) figures suggest a D_{16}/D_{50} ratio of 0.9. The difference in the results obtained with men and with rats is easily explained on the assumption that there is little natural variation with regard to the effects of blood alcohol on cerebral functions, but that a certain proportion of the human population acquire tolerance. Incidentally the results obtained by Bogen and Widmark provide fairly clear proof that the variation in tolerance to alcohol, which is such a familiar fact, is not merely due to differences in the rate of absorption, but that in addition there is a considerable individual variation in the effect produced by alcohol in the blood on the functions of the brain.

Measurements of the relation between the quantity of alcohol drunk and the incidence of intoxication would probably show a much wider scatter of individual variation than do the figures under discussion, because of wide differences in the rate of absorption of alcohol from the alimentary canal. Bogen's figures disclose a wider scatter of variation in the resistant half of the population than do Widmark's figures, but even in the case of the latter the distribution indicates that one individual in 1,000

would not be intoxicated by about four times the blood alcohol concentration that intoxicates 50 per cent. of the population.

Massive Digitalis Therapy

Digitalis preparations are standardized biologically on cats and on frogs, and figures for the variation in response of large populations are available. These figures show a very uniform response. The ratio D_{16}/D_{50} is about 0.9, and hence a dose equal to 73 per cent. of the mean lethal dose would kill only one individual in 1,000. Such results suggest that massive digitalis therapy may be a relatively safe procedure. There is, however, a very wide difference between a population of healthy cats and a population of patients with heart disease of varying intensity. Animal experiments prove that this apparent uniformity in response is obtained only when acute toxic effects are observed. For example, Bauer (1933) gave cats one-half a lethal dose of digitoxin, and then measured the amount of ouabain required to produce death twenty-four or forty-eight hours later. The individual variation with this latter dose was far greater than that found for the acute lethal action of these drugs. The ratio D_{16}/D_{50} was about 0.75, which indicates that one animal in 1,000 would be killed by 42 per cent. of the M.L.D. Similarly Li and van Dyke (1936) measured the individual variation in respect of cumulative poisoning in frogs. They gave doses of digitalis glucosides on alternate days, and their figures reveal a wide variation in the sum of the doses needed to produce death. The ratio D_{16}/D_{50} is about 0.4, and in this case a mortality of 1 in 1,000 would probably be produced by 1/16 of the M.L.D. Even with healthy animals, therefore, the uniformity of response to digitalis glucosides ceases as soon as opportunity is allowed for the action produced to be influenced by such factors as rate of excretion, etc.

The variability of the response of patients to digitalis therapy is well known; the following quantitative data give an indication of the scatter that occurs.

Murray Lyon and Gilchrist (1927) measured the changes produced in the heart rate by massive digitalis therapy. Their results show that the reduction in heart rate in cases of auricular fibrillation may range from 20 to 100 beats per minute, and that the greater the initial rate the greater was the reduction. In their group of thirty-seven cases with an initial heart rate between 70 and 100 per minute the reduction varied from 18 to 45 per minute in fibrillating cases, and from 0 to 40 per minute in non-fibrillating cases. Alstead (1936) noted the daily dose of powdered digitalis that produced nausea in thirty-six patients. In two nausea was brought about by 1 grain daily in a week, whilst in twenty-two cases 2 grains daily did not produce nausea in two weeks. Figures such as these indicate a wide individual variation in the response of patients to digitalis. The scatter of the variation appears to resemble the scatter observed in cumulative experiments on animals much more closely than the relatively uniform responses met with when the acute lethal dose of digitalis for animals is measured.

The question of practical interest is the probable margin of safety in massive digitalis therapy. The existing evidence is admittedly imperfect, but it suggests that in different individuals there is likely to be at least a fourfold range in the quantity of a drug required to produce a given effect. Consequently it appears to be very improbable that any method will be found of judging *a priori* the dose needed accurately enough to ensure that the average therapeutic dose will not produce severe overdosage in the occasional patient who is abnormally sensitive.

Conclusion

Individual variation is an unattractive subject because its existence constitutes a limitation to therapeutic measures of an annoying and irrational character. If a therapeutic method has produced satisfactory results in a dozen cases it seems irrational that the same technique should have an undesirable effect in the next case on which it is tried. It seems probable that the extent of individual variation is consistently under-estimated, because if an individual representing an extreme of variation happens to be encountered in a small group the result is apt to be discounted as an accident. The evidence available suggests, however, that whenever it is possible to measure quantitatively the effects produced by a drug in a large population an orderly distribution of variation in response is revealed. If this is the case, then the laws of probability indicate that if very large populations are studied occasional individuals will show very wide deviations from the mean response. These exceptional individuals are undoubtedly a nuisance from the clinical standpoint, but their existence must be recognized.

I feel that an apology is needed for the incomplete and inconclusive nature of the evidence collected in this paper. The examples chosen were the best I could find, and the result is evidence of the urgent need for fuller information regarding the distribution of human variation in response to drugs.

The Hon. Edward Cadogan, deputy chairman of the National Advisory Council set up by the Government to assist in the "National Fitness" scheme, gave an address recently at Harrogate in which he discussed the question of grants for projects of physical training and recreation. He said that when some local body was in need of funds for building a club, gymnasium, or swimming pool, or to lay out a recreation ground, its proposals would go before an area committee, which, after examination, would pass them on with comments to the Central Grants Committee in London. Grants would not be given to central organizations for distribution, but would be made directly in aid of particular local projects put forward by the voluntary organizations and by local authorities. In the Government's efforts to make a healthier and a fitter nation the element of compulsion would be entirely lacking. Mr. Cadogan ended with a tribute to local authorities and voluntary organizations for having done so much with meagre resources to supply the needs of those over school age; but the demand for means for physical training and recreation now far exceeded the supply.

FOOD REQUIREMENTS AND FOOD INTAKES*

BY

R. A. McCANCE, M.D., F.R.C.P.

AND

E. M. WIDDOWSON B.Sc. Ph.D.

(From the Biochemical Laboratory, King's College Hospital, London)

In quantitative work of any kind it is most important always to distinguish clearly between what is actually being measured and the deductions that are being made therefrom. This statement applies to the study of human food requirements and intakes just as much as it does to any other scientific investigation involving measurement, and the purpose of this article is to examine some of the assumptions and deductions commonly made in such work.

Food Requirements

As applied to food or food constituents the term requirement is used in several rather different senses. To most people the unqualified term "requirement" seems to mean the amount of any food constituent which will maintain an individual or a group of individuals in the *status quo ante* over a prolonged period of time. The term is used very loosely because the *status quo*, which is usually average health, is often presumed to be a state of perfect health, but in the absence of any tests must often not be so. This use of the term "requirement" is to be discouraged. The term "minimum requirement" permits of more precise definition, and may be stated for adults to be the least amount of any dietary constituent necessary to maintain a perfectly healthy individual in equilibrium for a given (usually a short) period of time. For children a separate definition is required. Here the minimum requirement is the least amount of any dietary constituent which will support an optimal rate of storage in the growing body.

The minimum requirements of many food constituents can be directly determined both in animals and man. The determination always involves some experimental departure from natural conditions, and the actual method varies with the particular food constituent to be investigated. Thus the determination of calorie requirements may involve a totally different approach and technique from the determination of the various mineral requirements. "Optimum requirements" for both adults and children are of far greater practical importance than minimum requirements, but they are exceedingly difficult to assess. They always exceed the minimum requirements by an allowance for foreseen and unforeseen eventualities. This allowance cannot be experimentally determined. In its assessment many independent lines of evidence may have to be considered, and the final decision is always a matter of judgement and will vary with the investigator. Everyone is agreed, however, that the requirements of different food constituents vary with age, sex, and occupation, and do not necessarily all vary in the same direction. Thus the calorie requirement rises with age up to puberty and thereafter varies with the amount of physical work performed. The calcium requirement, on the other hand, is certainly greater in childhood and adolescence than it is after growth has ceased, and is possibly greatest of all during pregnancy and lactation. Women's iron requirements are probably greater than men's throughout the whole of the child-bearing epoch. Vitamin requirements are admittedly greater during childhood than they are in later life, and, as with calcium, pregnant and nursing women rank with children in this respect.

Food Intakes

Food intakes are usually measured with a view to determining the chemical composition of the diet, although in some cases the kinds and amounts of the actual foods eaten are of primary importance. The determination of food intakes might appear at first sight a relatively simple matter, and so indeed it is, but even here assumptions are usually made. These can be reduced to a minimum if individual diets are weighed, and duplicate portions of all food and drinks are set aside and analysed by reliable chemical methods. In practice this is only possible if relatively few persons are studied. If individual diets are weighed and the composition calculated from food tables it is assumed that the composition of the foods eaten is the same as that of the foods analysed. This is certainly not the case, since the composition of different samples of the same food may vary widely. Experiments have shown, however, that the error introduced under favourable conditions is not a large one. Individual food intakes, therefore, can be assessed with a high degree of accuracy and the result regarded with a corresponding measure of confidence. They are not, however, synonymous with individual requirements and should never be so regarded, although they may be used, but only in special circumstances and with special precautions, as a guide to optimum and even minimum requirements.

In dietary investigations individual intakes have been little studied, and the usual procedure has been to determine the food intake of a group of persons. The accuracy with which this can be done varies with the group to be studied and the method to be employed, but, speaking generally, it can be done with an accuracy little, if at all, inferior to that attending the determination of individual intakes. If the experiment is performed on a group of persons of the same age and sex the average intake for that age and sex can readily be obtained. It is perfectly justifiable to average in this way, although, if one does, the value of the results is limited by the fact that the individual variations—which are of the greatest importance in medicine—remain quite unknown. The moment a less homogeneous group is selected for study difficulties begin to arise, not in the measurement of the food consumption of the group, but in the handling and interpretation of the data. Let us suppose that the group selected for study is a boys' school where the ages vary from 8 to 12. The results obtained expressed as averages on a per capita basis have considerably less significance than those obtained from the homogeneous group discussed above, because it is known that the intakes of boys of 8 are less than those of boys of 12. In most practical nutritional studies the difficulties are very much greater, for the unit or group commonly selected for study is the family, consisting generally of an adult of each sex and a variable number of children of different ages. To average family food intakes on a per capita basis is obviously of little scientific value. The following device was accordingly introduced many years ago and has been employed ever since.

Arbitrary scales for the food requirements of adults and of children of all ages and both sexes have been drawn up by various workers. The requirements of the family studied are worked out from one or other of these scales,

* Read in the Section of Nutrition at the Annual Meeting of the British Medical Association, Belfast, 1937.

and the sum of the individual requirements may then be compared with the family intake actually obtained. More usually the scale of requirements may be used to reduce the family intake to a unit value—the so-called "man value" basis. By these means one family may be compared with another and the manipulation of the results generally is greatly facilitated. Now let us consider the shortcomings of this method.

1. Many assumptions have to be made, even in the collection of the data.. If any members of the family take meals away from home the amount consumed by them is a matter of guesswork. The same applies if visitors are entertained during the period of investigation.

2. At best the "family" method gives only average results. Individuals within the group may not behave in the predicted manner, and the results obtained therefore have little or no individual significance. To cite a particular instance, if a mother were to starve herself to death for the sake of the other members of the family, the result would merely be a somewhat subnormal intake for the family on the "man value" basis.

3. The use of a scale of requirements to reduce an accurately measured group intake to a unit value is fraught with danger. Requirements are always a matter of judgement, and every investigator either selects one of the thirty-eight scales of requirements already proposed or introduces yet another more in keeping with his own ideas. When, therefore, the same family intake is reduced to a unit value basis, the results shown may vary by 30 per cent., according to the reducing scale adopted.

4. The scales of requirements in current use are scales of calorie requirements. Everything that we know about requirements indicates that a different scale of requirements should be used for each food constituent investigated. It is in fact a serious mistake to apply a scale of calorie requirements to evaluate intakes of calcium—or iron—or indeed of anything other than calories. This mistake, however, is still frequently made (Cathcart and Murray, 1936; Newcastle, 1936). It is no excuse to plead that requirement scales for calcium or iron are not in existence. Better far to give no results for these ions than to give results which are incorrect and misleading. Actually, scales have been drawn up on these lines, and that suggested by Stiebeling and Ward (1933) is probably the best in existence at the present time.

Conclusions

The food intake of a family may be ascertained with considerable accuracy, but the result has little meaning, and the reduction of this result to a unit value basis gives at best an average without individual variations and is achieved only by making some very daring and wholly unwarranted assumptions. Obviously the family method can never be used to assess requirements, since an arbitrary scale of requirements is invariably used in manipulating the results.

It is difficult indeed to understand why the family method of investigation has had such a vogue, but this point lies quite outside the scope of the present critique. The question is rather whether it should ever be used again. If no other method of studying food intakes were available there would of course be no question, but it is difficult to see what advantages, if any, the family method has over the individual method. Any result obtained by the former technique can be obtained with greater accuracy and without assumptions by the latter. The individual method of study is not difficult, and we would urge those desirous of making nutritional investigations to give it a trial rather than to follow slavishly a method the results of which are so very difficult to interpret.

THE TREATMENT OF NON-STENOSING PEPTIC ULCER*

BY

JOHN MORLEY, Ch.M., F.R.C.S.

Professor of Surgery, Manchester University; Honorary Surgeon, Manchester Royal Infirmary

This discussion has been limited advisedly to the treatment of non-stenosing peptic ulcer, because where stenosis has established a mechanical obstruction there can be no difference of opinion as to the appropriate treatment. Mechanical obstruction demands surgical relief.

In the treatment of non-stenosing ulcers there has been a movement during the past decade, in practice rather than in opinion, towards conservative measures. The best surgical opinion has always upheld a sane conservatism. It was a favourite *obiter dictum* of Lord Moynihan's that he never operated on a case of duodenal ulcer until it had been cured nine times by a physician. But there is no doubt that some years ago there were numerous surgeons who regarded all chronic peptic ulcers as suitable grist for their mill, though, being what are known as "practical surgeons," they were not given to airing their views in the medical literature. The swing of medical opinion that has effectually prevented this wholesale and indiscriminate operating upon non-stenosing ulcers is, it will be agreed, a good thing. But in a discussion such as this we should not be influenced greatly by the vogue of the moment, but should seek to inform medical opinion on the more controversial points of treatment, and to lay down clear and precise indications as to the place of surgery in this field.

The change in practice to which I have alluded has been brought about partly by the unfortunate results of indiscriminate surgery, but chiefly by improved medical technique. The almost universal use of fractional gastric analysis has provided a much better guide to treatment than to diagnosis. Far more attention has been devoted to diet, and it has been widely realized that diet is more important than alkalis in the continuous neutralization of hyperchlorhydria which is the aim of medical treatment. There is also a praiseworthy tendency in many quarters to test the results of medical treatment by repeated radiological studies, though, as we shall see later, there are dangers in placing too much reliance on the picture of an ulcer crater.

These advances in medical technique compel our admiration and approval. A less admirable development of recent years has been the widespread use by patients of the various proprietary alkaline powders and medicines, often in large doses over a prolonged period and often with serious toxic results. On the recent vogue of treatment by histidine injections I will merely say that in my

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Belfast, 1937.

judgement it has no convincing scientific foundation save that of psychotherapy, and venture to predict that it will soon have its day and cease to be.

Duodenal Ulcer

The proper treatment of non-stenosing duodenal ulcer is medical. Few, I imagine, will dispute this statement, or deny that if the medical treatment is thorough, including an adequate period of rest in bed at the start and the most punctilious regulation of diet and manner of life in the later stages, the results will usually be good. But cases are not uncommon in which medical treatment fails because the patient is unable or unwilling to carry out instructions as to diet, or for various other reasons. When medical treatment has repeatedly failed or is for social reasons impracticable, ought we to refuse the patient the benefit of surgery until, after years of suffering, he can provide evidence of pyloric stenosis? Some would answer "Yes," but I would not count myself as one of these pessimists.

Another indication for surgery in duodenal ulcer is the occurrence of severe haemorrhage, in one or more attacks. I do not now advocate operation during or immediately after a grave haemorrhage, for I believe the risks are too great. But a serious haemorrhage is very prone to recur, and our aim should be to prevent the chance of a recurrence if we can do it with reasonable safety. The grave emergency can generally be tided over by blood transfusion, and then, when the pulse rate and volume and haemoglobin percentage show that we can operate with safety, we should not delay longer if the patient is on general grounds a good surgical risk and if we are sure that he has a chronic ulcer. I do not dwell on acute perforation as an indication for surgery, since that is outside the realm of controversy.

The Choice of Operation for Duodenal Ulcer

We have not solved the problem, however, when we have laid down the indications for operation. An equally important question is, What operation should we perform? Where the main indication for operation is the prevention of recurrent haemorrhage I am sure that the right answer is this, that the first essential is to excise the ulcer, and with it the vessel that has been bleeding. Gastro-enterostomy alone is a very ineffective operation for a bleeding duodenal ulcer, and gastro-enterostomy combined with excision of the ulcer is both difficult and dangerous. The most effective method of excising the ulcer is to include the first part of the duodenum in some form of gastrectomy. This both controls the source of the bleeding and averts the danger of a recurrence. But where the ulcer is a penetrating one on the posterior wall of the duodenum with great surrounding fibrosis its excision may involve too much danger. In such cases it may be more prudent to leave the ulcer alone, divide the pre-pyloric portion of the stomach some two inches above the pyloric sphincter, and do a high Polya gastrectomy. The ulcer will be left in a cul-de-sac of duodenum removed from contact with acid gastric juice, and may be relied upon to heal without delay.

We must now consider the choice of operation for simple non-stenosing duodenal ulcers with no history of haemorrhage. It is comparatively rarely that we are called upon to operate on such cases, but in recent years opinion has been more divided as to the best operation to perform in this condition than upon any question in gastric surgery. We may, I think, exclude from our consideration such operations as gastro-duodenostomy in its various forms, which have never achieved great popularity among surgeons in these islands, and other "fancy operations," and limit our attention to the question of posterior gastro-enterostomy versus gastrectomy. Posterior gastro-enterostomy is an operation with a very low mortality—not more than 2 per cent. in competent hands—and the vicious-circle vomiting so often met with twenty years ago has been eliminated by modern technique; but over it hangs the dread of gastro-jejunal ulcer, and gastro-jejunal ulcer is a far worse calamity than the duodenal ulcer to which it may succeed. What is the risk of this calamity after a posterior gastro-enterostomy? The most careful and comprehensive inquiry into this problem was the collective investigation carried out for the Fellows of the Association of Surgeons of Great Britain and Ireland by Garnett Wright and published in 1935. In a series of 1,730 cases of duodenal ulcer treated by posterior gastro-enterostomy he found an incidence of gastro-jejunal ulcer amounting to 8.49 per cent. But there are certain difficulties in accepting this figure as the whole truth. No fewer than 1,004 other cases were untraced, and it is a matter of speculation whether that large number contained a higher or a lower incidence of gastro-jejunal ulcers than the cases that were traced. My own opinion, for what it is worth, is that the incidence would be somewhat higher. Then there was a series of 507 gastric ulcers in this investigation with the surprisingly high incidence of 10.45 per cent. of gastro-jejunal ulcers. This is surprising, for the reason that operations for gastric ulcer are in the experience of most surgeons far less likely to be followed by gastro-jejunal ulcer than are operations for duodenal ulcer. Garnett Wright very justly ascribed this anomaly to the inclusion in this gastric group of many "pyloric ulcers" that should more properly have been described as duodenal. A correction of this classification, had it been possible, would have swollen still further the incidence of gastro-jejunal ulcer. I think it is not unfair to conclude that if we take the work of surgeons of repute all over the country we may consider that posterior gastro-enterostomy for duodenal ulcer is followed by gastro-jejunal ulcer in about 10 per cent. of cases. I do not forget that Sir James Walton (1934), in a personal series of 893 duodenal ulcers, all of which were traced, found only 3.24 per cent. of gastro-jejunal ulcers; but that is gastric surgery at its best, and I suggest the figure of 10 per cent. for gastric surgery of good average quality. Some may estimate the incidence as even higher.

This conclusion is a grave indictment against the operation of posterior gastro-enterostomy for the non-stenosing duodenal ulcer, and this is the reason why many surgeons in this country, and I think more surgeons on the Continent, are abandoning gastro-enterostomy except where stenosis is present. There is good evidence for the belief that gastrectomy, by permanently lowering the secretion of hydrochloric acid, involves a much lower risk of anastomotic ulcer later, but it is a more difficult operation, with a higher mortality, and is certainly no operation for the occasional surgeon.

What is the operative mortality of gastrectomy for duodenal ulcer? It is higher, I believe, than that of the same operation when performed for gastric ulcer, because of the greater technical difficulties, and it may be estimated as somewhere in the region of 6 per cent. But it is essentially capable of reduction in competent and experienced hands, though it is too much to hope that gastrectomy for duodenal ulcer will ever carry as low an operative mortality as gastro-enterostomy.

The conclusion I submit is the following. Where the gastric analysis shows a high hydrochloric acid curve, as it commonly does in young men with duodenal ulcer, the

risk of gastro-jejunal ulcer later is so grave that we should do a high gastrectomy, preferably of the Polya type. In duodenal ulcer in women the risk of recurrent ulcer is much less, and here, if the test meal shows a low acid curve, gastro-enterostomy is a very satisfactory operation. In elderly patients who are poor risks by reason of cardiac or pulmonary degeneration there is also less danger of recurrent ulcer, and where some operative measure is inevitable the less severe operation of gastro-enterostomy should be performed.

Gastric Ulcer

Although gastric ulcers share with duodenal ulcers a common, and largely uncertain, aetiology, their surgical treatment presents very different problems. As we have seen, our treatment of a duodenal ulcer is conditioned by the fear of a more or less remote gastro-jejunal ulcer. Operations for gastric ulcers, however, because of the much lower gastric acidity, are very rarely followed by anastomotic ulcers. But gastric ulcers carry their own special nightmare—the dread of carcinoma. Carcinoma in the first part of the duodenum is so rare that it may almost be said not to occur there, nor does a cancer of the pyloric end of the stomach ever spread into the duodenum. But the stomach is the commonest site of cancer in the body.

The Relation of Gastric Ulcer to Cancer

The danger of cancer supervening on a chronic gastric ulcer has been greatly exaggerated in many quarters. It is a long time since Wilson and MacCarty (1909) of the Mayo Clinic startled the medical world by the statement that 68 per cent. of all gastric ulcers removed at operation showed microscopical evidence of malignancy, and that 71 per cent. of all gastric carcinoma showed pathological evidence of a preceding simple ulcer. It has been proved by many succeeding investigators, approaching the problem from both the pathological and the clinical aspects, that the incidence of the so-called ulcer-cancer is far smaller than Wilson and MacCarty claimed. The site of election of gastric ulcers, which are mostly on the lesser curvature, differs in a striking way from that of cancer, which occurs most commonly near the pylorus, and Stewart's investigations on this point are visualized on the accompanying diagrams (Figs. 1 and 2). Stewart (1931), in a series of 277

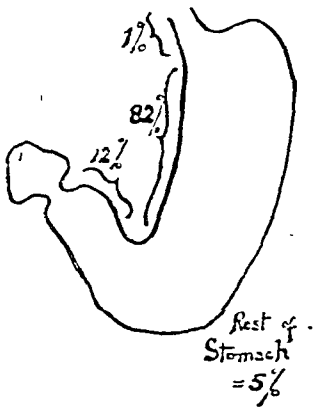

FIG. 1.—Site of ulcer.

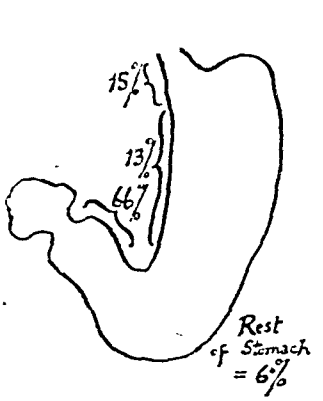

FIG. 2.—Site of carcinoma.

chronic ulcers removed by operation, found evidence of early carcinoma in 6.1 per cent. Newcomb (1932), in another careful pathological investigation, showed that 3.5 per cent. of gastric ulcers showed an early malignant change. My own opinion, based upon both histological and clinical evidence, is that malignant transformation of a simple gastric ulcer is a very rare event. In a series of fifty-four cases of proved cancer of the stomach I found (1923) that the average duration of gastric symptoms before examination was 12.7 *months*, whereas in forty-five cases of proved simple chronic ulcer the average duration of symptoms was 10.3 *years*.

It is not, I would suggest, the frequency with which they become malignant that should influence our attitude to the treatment of gastric ulcers so much as the difficulty in many cases of arriving at an accurate diagnosis between simple and malignant ulcers. There is a type of slow-growing cancer of the stomach, by no means uncommon, which very closely simulates the clinical picture of gastric ulcer. In these cases the pain is at first periodic in character, and is relieved both by food and by alkalis. Appetite is often retained, and the gastric analysis in the early stages shows a high or normal acidity. The growth may be regarded as a simple ulcer for a year or two, and yet is a carcinoma from the beginning. The radiological appearance may be either doubtful or suggestive of simple ulcer.

In view of the rarity of simple ulcers and the frequency of carcinomata in the pyloric region lesions in that position that appear to be simple ulcers should always be regarded with suspicion. It is a sound rule that where a pre-pyloric ulcer has been treated medically for three weeks, and there is still occult blood in the stools, gastrectomy should be performed. Whenever a patient of cancer age presents a considerable ulcer crater in any part of the stomach with a short history of gastric pain a suspicion of malignancy should be entertained, no matter how innocent the radiological appearance may be. The following case illustrates this point dramatically.

A lady aged 60 consulted her doctor complaining of vague epigastric pain of a few weeks' duration and some loss of weight. She had never suffered from indigestion before. A radiograph showed a penetrating ulcer in the middle of the lesser curvature that was regarded as simple. Medical treatment was advised. Six weeks later she was rather better, and had put on a few pounds in weight. A second radiograph now showed that the ulcer crater was nearly filled up. After a further three months she was again losing weight and feeling rather more discomfort, in spite of medical treatment. A third radiograph taken less than six months from the onset of symptoms showed a definite carcinoma at the site of the original ulcer crater. I explored the abdomen and found widespread secondary deposits in the peritoneum, and was unable to do anything. It is certain, I think, in spite of the earlier *x*-ray appearance, that this was a carcinoma from the beginning.

Such a case teaches us most eloquently that in gastric surgery clinical history may be more reliable than radiological signs.

Whether the wider use of the flexible gastroscope will prove of great value in this difficult matter of distinguishing simple from malignant ulcers I do not know. When I think of the number of cases I have seen in which the innocent naked-eye appearance of the specimen after resection has been falsified by the microscopical evidence of malignancy, I am doubtful.

Quite apart from the urge that the fear of cancer gives us to radical measures for gastric ulcers, the results of surgical treatment of ulcers in this field are more favourable than in the non-stenosing duodenal ulcers. This is mainly attributable to the fact that in gastric ulcers we find a much lower average acidity than occurs with duodenal ulcers, and consequently there is comparatively little danger of recurrent or anastomotic ulceration. Medical treatment, on the other hand, especially in the larger ulcers, is often followed by relapse after relapse.

Choice of Operation in Gastric Ulcer

It will be agreed by most surgeons that simple gastro-enterostomy is not a satisfactory operation for gastric ulcer. Although it will produce brilliant results in a proportion of cases it is too often followed by recurrence. And any operation that fails to excise the ulcer gives no safeguard against the development of a cancer if the diagnosis should be mistaken. Gastro-enterostomy is not enough. Simple excision of the ulcer also stands condemned because it leaves unaltered the physiological conditions that led to the formation of an ulcer, and is followed in a large proportion of cases, as we might expect, by recurrence. Excision of the ulcer combined with gastro-enterostomy is a much more satisfactory operation, but its results are in no respect better than those of partial gastrectomy, and it is often a much more difficult operation to perform. For this reason I now find myself doing it very rarely.

The operation of choice for any accessible chronic ulcer in the stomach is undoubtedly some form of partial gastrectomy. On this main question there is very general unanimity among surgeons. It is only when we come to discuss the precise method of performing the gastrectomy that differences of opinion appear. This is not the place to discuss the minutiae of surgical technique, but the choice lies between some form of Billroth I operation in which the stump of the stomach remaining is anastomosed with the first part of the duodenum, or some variety of the Polya gastrectomy (including Finsterer's operation) in which the stomach is united to the side of the first jejunal loop. There is perhaps no very fundamental principle involved, and every surgeon will tend to get the best results with the type of operation in which constant practice has steadily improved his technique. My own preference is decidedly in favour of that modification of the Billroth I operation associated with the name of Schoemaker. It has the advantages that it is simple to perform, it is less destructive of gastric function than the Polya operation, and it is therefore less liable to be followed by a severe degree of achlorhydric anaemia. I repeat that each surgeon will be guided chiefly by his practical experience. My own experience is that the Schoemaker gastrectomy is the safer operation. For gastric ulcer I have performed the Polya operation only forty-seven times with three deaths, a mortality of 6.4 per cent., while I have performed the Schoemaker operation 171 times with five deaths, a mortality of 2.9 per cent.

I submit that a method of gastrectomy involving a mortality of less than 3 per cent. is getting near to the ideal that it should be as safe as gastro-enterostomy. The convalescence is always smooth and uneventful, and the late results are good in a very high proportion of cases. I have a record of only one anastomotic ulcer following the Schoemaker operation in my own series. For the large ulcers extending high up on the lesser curvature I find this operation rather more feasible than the Polya, because one is not compelled to use the fibrosed lesser curvature adjacent to the ulcer in making the anastomosis.

Treatment of Gastro-jejunal Ulcer

There is no comparison between the ease of operating on a gastric or duodenal ulcer that is, so to speak, virgin soil for the surgeon and the difficulty of an operation for an anastomotic ulcer. To undo the gastro-enterostomy, excise the ulcer, and restore the stomach and jejunum to their original state is often a long and arduous undertaking, so that a surgeon who has accomplished it is tempted to be content and to close the abdomen. But if he does the original duodenal ulcer may usually be relied upon to re-form, and if later another gastro-enterostomy should be undertaken for its relief the gastro-jejunal ulcer will almost inevitably recur.

There is only one satisfactory operation for a gastro-jejunal ulcer that resists all medical treatment, as a good many of them do, and that is to undo the gastro-enterostomy and then to proceed to perform a high Polya gastrectomy. Only by abolishing the gastric function and removing the oxyntic cells as completely as possible can the vicious circle be broken. There is no more formidable operation in the surgery of the stomach, particularly where a gastro-colic fistula has to be closed in addition. The mortality is a very considerable one, but for those patients who come safely through the operation the prospects of a permanent cure are extremely good.

THE VALUE OF PATERNITY EXCLUSIONS MADE BY THE BLOOD-GROUPING TEST

BY

JOHN C. THOMAS, M.R.C.S., L.R.C.P.

Serologist to the Metropolitan Police Laboratory, Hendon

With the increasing demand for the introduction of legislation in this country to allow of the use of the blood-grouping test in all paternity cases it is desirable to examine the test in greater detail to see exactly what it will do. It is unnecessary to discuss in detail the method of inheritance of the blood groups, as this has recently been done by other authors (Harley and Roche Lynch, 1937, 1937a), but it may conveniently be summarized in four laws, two relating to the ABO system and two to the MN system. The heredity of the ABO system is dependent upon three allelomorphic genes, A, B, and O, of which A and B are dominant over the recessive O. The MN system is inherited by two genes, M and N, each of equal dominance. Thus we have the four main blood groups, A, B, AB, and O, each of which may be further subdivided by the independent MN system into M, N, or MN.

The Laws of Inheritance

The laws of inheritance which have been formulated from the investigation of many thousands of families are:

ABO.—(1) The factors A and B cannot appear in the blood of a child unless they are present in the blood of one or both parents. (2) The combinations AB parent and O child, and vice versa, are incompatible with the laws of heredity of the group factors.

MN.—(1) The factors M and N cannot appear in the blood of a child unless they are present in the blood of one or both of the parents. (2) The combinations M parent and N child, and vice versa, are incompatible with the laws of heredity of the group factors.

The groups A and AB may be further subdivided into A_1 and A_2 and A_1B and A_2B by the use of appropriately absorbed group B or normal animal sera. This observation was first made by von Dungern and Hirsch-

feld in 1911, and from it has arisen the accurate subgrouping of the factor A; A_1 being the "strong" A and A_2 the "weak" A. Recently Friedenreich (1936) has demonstrated the existence of a still weaker type of A receptor, which he calls A_3. All these factors are inherited according to simple Mendelian laws, A_1 being dominant over A_2, which in turn is dominant over A_3. I propose to ignore the A_3 group, as the factor is extremely rare and very few families have so far been investigated. However, with the introduction of the A_1–A_2 system into paternity cases we have a greatly increased probability of exclusion based upon four further laws:

A_1–A_2.—(1) The agglutinogen A_1 cannot appear in the blood of a child unless it is present in the blood of one or both parents. (2) The combinations A_1B parent and A_2 child, and vice versa, are incompatible with the laws of heredity of the group factors. (3) In the special matings $A_1B \times B$ and $A_1B \times A_1B$, A_2B children cannot result. (4) Where several children are available in each mating further special exclusions are possible with the following five special crosses: $A_1 \times O$, $A_1 \times A_1$, $A_1 \times B$, $A_1 \times A_1B$, and $A_1 \times A_2B$. In these matings, if there is one child belonging to either group O or B none of the remaining children can be of group A_2 or A_2B, and conversely. This is easily understood from a consideration of the genotypes of the parents concerned (Table I).

We are dealing, therefore, with two independent genetic systems (the ABO and A_1–A_2 systems may conveniently be taken together), the genotypes of their various constituent groups being shown in Table I.

TABLE I.—*Composition of the Blood Groups.*

Genotype	Phenotype	Genotype	Phenotype
A_1–A_2 system:		ABO system:	
A_1A_1	A_1	AA	A
A_1A_2		AO	
A_1O			
A_2A_2	A_2		
A_2O			
A_1B	A_1B	AB	AB
A_2B	A_2B	BB	B
		BO	
MN system:		OO	O
N_1N_1* MM	M		
N_2N_2 NN	N		
MN_1 MN	MN		
MN_2			

* The N_2 type is discussed under exclusion type 4. No person corresponding to N_2N_2 has yet been demonstrated.

It is upon these laws of inheritance that the possibility of making paternity exclusions is based. There are, however, certain reservations attached to some of the exclusions, and I propose to discuss each of the various types of exclusion in detail, starting with the strongest and going down to the weakest.

Types of Exclusion

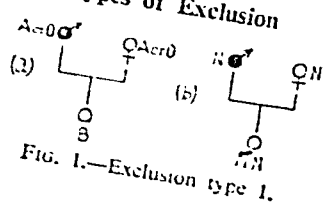

FIG. 1.—Exclusion type 1.

In these two cases the exclusion of the man from paternity is so strong as to be almost absolute. In case 1a we know that the father must possess the B factor, and in case 1b he must possess the M factor, neither of which obtains with the men in question. Both the B and the M factors are extremely stable, and there is no reason to suppose that they are ever suppressed—that is, fail to appear in the phenotype although actually present in the genotype. This exclusion, therefore, is the strongest which is compatible with the accuracy of the test.

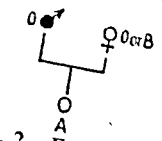

FIG. 2.—Exclusion type 2.

This exclusion, although apparently the same as type 1, is in fact slightly weaker. This will become obvious after discussion of type 3.

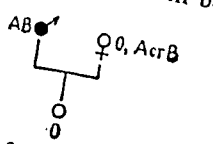

FIG. 3.—Exclusion type 3.

Haselhorst and Lauer (1930, 1931) described a case of an AB mother whose child had persistently remained group O. This is the only proved exception to the ABO system that has been demonstrated, all the other reported exceptions of the same type showing a latent development of the specific factors in the child. In the Haselhorst case, as the child was blind at birth, was markedly deformed, and suffered from a severe anaemia, the anomaly is probably due to a failure in the development of the agglutinogen in the child. The mother was of group A_2B, and in view of the stability of the B factor it is probably the A_2 factor which has not developed—that is, the child is a "latent" or "repressed" A_2, which may later become manifest or may remain hidden throughout his life.

Exclusion type 3 is really a Haselhorst case against the father, and in estimating the value of the exclusion we have to take into account the possibility of a recurrence of the Haselhorst case. Owing to the comparative rarity of group AB, relatively few AB mother–child combinations have been investigated (1,500), whereas 15,000 group O mothers have been examined, none of their children being of group AB. The estimated chance of the failure of a dominant gene in the genotype to develop phenotypically is less than 1 in 10,000, so that, even bearing in mind the possibility of an exception, the value of the exclusion is still very great. It cannot, however, be as absolute as that of exclusion type 1.

Suppose, now, that a person did contain a suppressed A gene which was not apparent in the phenotype. It is possible, if he married, that he might transmit the suppressed gene, which in the next generation might assume its normal dominance and become apparent in the phenotype. Thus it is remotely possible for two group O parents to have a group A child if this eventuality came to pass. Such a case is envisaged in exclusion type 2, in which a group O man is to be excluded as the father of an A child, the mother being either O or B. The chance of such an occurrence is extremely remote, being obviously even less than that of the Haselhorst case, but to be entirely accurate a "formal reservation" in these cases should be made.

It is possible that type 3 of the exclusions may operate against the mother in a paternity case, and if an AB mother is found with an O child in such a case there is a very strong probability that the child is not the natural child of the woman but has been adopted for the purposes of blackmail. Such a case is recorded by Wiener in

New York, where he was able to show that the woman was not the mother; she withdrew her charges against the defendant and the case was stopped (personal communication).

This type of exclusion may be further divided by the A_1–A_2 system:

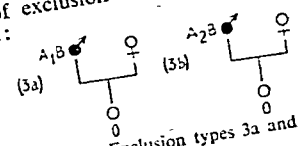

FIG. 4.—Exclusion types 3a and 3b.

The A_1 factor is very much more stable than the A_2 and is more on a par with the B factor in its exclusion power. Thus the exclusion type 3a is almost as strong as type 1, whereas type 3b, in which exclusion has to be made on account of the A_2 factor, is equivalent to the Haselhorst case and requires a definite reservation in assessing its value.

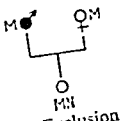

FIG. 5.—Exclusion type 4.

This again appears superficially to be an absolute exclusion, the N factor not being present in either of the parents. Crome (1934), however, described a 19-year-old mother of group OM with an 18-months-old child of group ON, and this apparent exception was confirmed by a number of workers. Thomsen examined the mother with exceptionally strong sera and found that she actually possessed a very weak N receptor as well (analagous to the A_2 factor), and he classified her as OMN_2. The father was an N, so that the child's genotype became NN_2 instead of the MN which was expected. Friedenreich (1936a) has investigated a number of families in which the N_2 receptor is present, and has shown that in fact the MN system is represented by three genes—M, N_1, and N_2—instead of just M and N as was previously supposed. Of these N_1 is dominant over N_2 in the same way as A_1 is dominant over A_2.

In this exclusion type the possibility is that either of the parents may be MN_2, the N_2 receptor being suppressed in them but becoming dominant again in the child. There is a second possibility—that the N_2 factor might be missed by the use of too weak test sera. The possibility of suppression of the N_2 factor is the same as that for the suppression of the A_2 factor, and requires only a formal reservation in interpreting the value of the exclusion. The possibility of an error in technique outweighs the possible error in genetic transmission. It is therefore essential that blood-grouping tests, when used for medico-legal purposes, should be entrusted only to competent experts who have the requisite apparatus and sera continually in use under properly controlled conditions (Thomas, 1937).

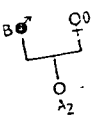

FIG. 6.—Exclusion type 5.

Here again a factor (A_2) is present in the child but is not present in the blood of either the mother or the putative father. The A_2 factor is a weak one and may easily be missed, especially if it is present in conjunction with the more powerful B receptor. As an instance of this I may give my own blood group. As a matter of interest a year ago I was grouped by three persons independently. The first told me I was a group O—his sera were useless, being totally inactive; the second informed me I was a group B—his anti-A serum was of low titre and reacted with A_1 only as far as a dilution of 1 in 2, and with A_2 not at all; the third correctly grouped me as an AB, although even with his potent sera the A reaction was not marked. In fact, the correct group is A_2B, so that there is a very real possibility of error in failing to detect the A_2 in an A_2B blood. Unless this possibility is excluded by the use of properly controlled sera of high titre the value of the exclusion is lost.

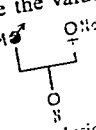

FIG. 7.—Exclusion type 6.

Here, at first sight, the man may be excluded, as his blood contains no N receptor. The exclusion is similar to that of type 4, the same reservation applying to both, the possibility being that the man may be an MN_2, in which case the child could be genotypically N_1N_2. Although it appears exactly similar to type 4 it is in fact a slightly different exclusion. In this case the child is N_1N_2, inheriting an easily demonstrable factor from the mother, the possibility of error arising from the failure to demonstrate the weak N_2 in the alleged father. In type 4 the exclusion is obviously stronger, for if the child is MN_2 and one of the parents is MN_2 there is no reason why the N_2 should be demonstrated in the one and not in the other. Thus the possibility of technical error is greater in type 6 than in type 4.

In effect the exclusion made by type 6 is the case which Crome described, and the possibility of error must always be borne in mind. The error, however, is one of technique rather than of heredity, and as such should be guarded against and overcome.

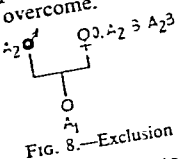

FIG. 8.—Exclusion type 7.

This is an immediate exception to the laws of inheritance of the A_1–A_2 system, in that A_2 is not present in either the mother or the alleged father. The reservation which must be made in these cases is again one of the possibility of error in technique, and unless the criteria of proper technique are satisfied and unless the reactions obtained the exclusion cannot stand.

FIG. 9.—Exclusion type 8.

No importance should be attached to this exclusion type owing to the possibility of technical error at the present time.

Considerations in Evaluation

In general the following considerations apply in the evaluation of paternity exclusions by the blood-grouping test.

ABO System

By far the most complete investigations of the heredity of the blood groups have been made with the ABO system, and out of the many tens of thousands of families examined only one exception to the accepted laws of transmission of the group factors has been demonstrated (the Haselhorst case). The possibility of the recurrence of such a case is so slight that *paternity incompatible with the ABO system must be excluded with as great a degree of certainty as a biological method can give.* It is justifiable to leave the Haselhorst case out of consideration unless there are quite exceptional circumstances, apart from the blood-grouping test, which indicate that the paternity is established.

TABLE II.—*Paternal Exclusions by the ABO and A_1–A_2 Systems*

Mother	Child	Father	
		Possible	Impossible
O	O	O, A_1, A_2, B	A_1B, A_2B
O	A_1	A_1, A_1B	O, A_2, B, A_2B
O	A_2	A_1, A_2, A_2B	O, B, A_1B
O	B	B, A_1B, A_2B	O, A_1, A_2
A_1	O	O, A_1, A_2, B	A_1B, A_2B
A_1	A_1	All groups	None
A_1	A_2	O, A_1, A_2, B, A_2B	A_1B
A_1	B	B, A_1B, A_2B	O, A_1, A_2
A_1	A_1B	B, A_1B, A_2B	O, A_1, A_2
A_1	A_2B	B, A_1B, A_2B	O, A_1, A_2
A_2	O	O, A_1, A_2, B	A_1B, A_2B
A_2	A_1	A_1, A_1B	O, A_2, B, A_2B
A_2	A_2	O, A_1, A_2, B, A_2B	A_1B
A_2	B	B, A_1B, A_2B	O, A_1, A_2
A_2	A_2B	B, A_1B, A_2B	O, A_1, A_2
B	O	O, A_1, A_2, B	A_1B, A_2B
B	A_1	A_1, A_1B	O, A_2, B, A_2B
B	A_2	A_1, A_2, A_2B	O, B, A_1B
B	B	All groups	None
B	A_1B	A_1, A_1B	O, A_2, B, A_2B
B	A_2B	A_1, A_2, A_2B	O, B, A_1B
A_1B	A_1	All groups	None
A_1B	B	All groups	None
A_1B	A_1B	A_1, B, A_1B, A_2B	O, A_2
A_1B	A_2B	A_1, A_2, A_2B	O, B, A_1B
A_2B	A_1	A_1, A_1B	O, A_2, B, A_2B
A_2B	A_2	O, A_1, A_2, B, A_2B	A_1B
A_2B	B	All groups	None
A_2B	A_1B	A_1, A_1B	O, A_2, B, A_2B
A_2B	A_2B	A_1, A_2, B, A_1B, A_2B	O

A_1–A_2 SYSTEM

Here the available family material is considerably smaller than that of the other two systems, but there can be no doubt as to the correctness of the genetic hypothesis which has been advanced. In a few persons the red cells give atypical reactions so that they cannot be classified sharply into either group A_1 or A_2, and no conclusions ought to be drawn from them by the A_1–A_2 exclusion system. When, however, the group reactions are quite typical the possibility of a man being the father in fact when he has been excluded by the A_1–A_2 system is exceedingly slight. The possibility of A_1 being mistaken for A_2 in rare cases cannot, however, be entirely ruled out, although it is very remote if the examination is properly conducted by agglutination *and* absorption tests, and typical reactions have been obtained. It is not safe at the present time to consider a paternity incompatible with the A_1–A_2 system as excluded with biological certainty; it is, however, justifiable to regard such incompatibility as *strong circumstantial evidence of non-paternity*.

Owing to the possibility of technical error, the diagnosis of group A_2B is less reliable than that of group A_2, although the diagnosis of group A_1B is quite as reliable as that of group A_1. If a paternity is incompatible with the A_1–A_2 system because one of the parties is of group A_2B (while no exclusion could have been made had this person been of group A_1B) *it is not justifiable at present to consider the paternity so improbable that a decisive importance may be attached to the blood grouping in such a case.*

MN SYSTEM

The material available here is already large and is steadily growing. Although the system has been widely investigated for ten years now, it was not until three years ago that the N_2 factor was discovered. This factor is extremely rare, and is characterized by an abnormal but inherited weakness of the N receptor; one has always to consider the possibility that it may escape detection with a resulting erroneous exclusion. This, however, only applies to certain of the parent-child combinations (exclusion types 4 and 6).

The remaining exclusions made by this system are not affected, as paternity would still be incompatible even if there were a concealed N_2 receptor in one of the parties. In these cases a *paternity incompatible with the MN system may be excluded with as great a degree of certainty as a biological method can give.*

List of Paternal Exclusions

All the possible exclusions are given in Tables II and III, Table II showing the combined exclusions by the ABO and A_1–A_2 systems, and Table III those by the MN and N_1–N_2 systems.

TABLE III.—*Paternal Exclusions by the MN and N_1–N_2 Systems.* (After Thomsen, 1936.)

Mother	Child	Father		
		MN System (old)		M–N_1–N_2 (new)
		Possible	Impossible	
M	M	M, MN	N	If the child is MN_2 the father may be NN_2 or possibly N_2N_2. Thus N cannot be excluded with certainty
M	MN	N, MN	M	M still excluded
N	N	N, MN	M	If the child is NN_2 the father may be MN_2, so that M cannot be excluded with certainty
N	MN	M, MN	N	N still excluded
MN	M	M, MN	N	If the child is MN_2 the father may be NN_2 or possibly N_2N_2. Thus N cannot be excluded with certainty
MN	N	N, MN	M	If the child is NN_2 the father may be MN_2, so that M cannot be excluded with certainty
MN	MN	All	None	Theoretically a N_2N_2 father may be excluded. This is of no practical significance
M	N	The mother may be MN_2, and the child may receive its N from the father. Thus all M men are excluded. If the father is MN_2 the child can be N_1N_2		
N	M	The mother may be NN_2, and the child must be MN_2. In this case the father must be M or MN. Thus all N men are excluded		

Summary

1. The value of each type of paternity exclusion has been discussed.

2. In most cases the possibility of error is that of an error in technique rather than a deviation from the genetic laws which govern the heredity of the group factors, and as such should be properly guarded against.

3. The appropriate reservations for each type of exclusion have been discussed.

I am greatly indebted to Professor Dr. Knud Sand and Dr. V. Friedenreich of the Universitets Retsmedicinske Institut, Copenhagen, for their valuable assistance in the preparation of this paper.

Gruber, Planckstrasse 8, Göttingen.

TECHNIQUE OF CATARACT EXTRACTION DURING NARCOSIS*

BY

BASIL GRAVES

Operations on the interior of the adult eye are performed with the patient awake, particularly in the case of cataract extraction. This is because with the usual operative technique the co-operation of the patient is necessary to supplement the control of the position of the eye, and the congestion, vomiting, and other disturbances commonly associated with general anaesthesia entail risks to the eye. The mental strain on the average elderly person of consciously submitting to a cataract operation is considerably more than is realized. Medical thought is accustomed to the use of local anaesthesia, the patient remaining fully conscious, and to the extreme degree of unconsciousness of general anaesthesia. But attention has not been given to the attainment of a less extreme state of somnolence, in which, besides being given the usual local injection of novocain, the patient may also be put to sleep to a degree sufficient to abolish all consciousness of the proceedings. "Surgical narcosis" might be a suitable name for such an intermediate state.

The purpose of this article is to describe, first, a routine technique—which I have employed for a long time—for rendering the patient quietly unconscious during operations on the interior of the eye. The state of sleep lasts for some seven to fourteen hours after operation—a period in which pain is commonly experienced after the effect of the usual local anaesthetic has disappeared. The patients wake up as from a long normal sleep, with no pain in the eye and seldom with any unpleasant general sensations. Secondly, I propose to describe briefly a modification of the operative technique of cataract extraction, which meets these conditions of narcosis, adds safety to the orthodox method, and has the advantage that the patient can safely be propped up in bed on the next day and can sit out of bed usually on the third day instead of staying in bed for the customary seven days.

Elderly persons, especially women, after cataract operations may experience serious symptoms such as vomiting, flatulence, abdominal pain, and constipation, which are usually attributed to the absence of peristalsis due to lying on the back for many days. Delirium may follow cataract extraction done with the patient awake, as may urinary retention. If patients who have not had cataract operations lie flat for days they do not get the same, if any, distressing symptoms. In my experience these symptoms do not ensue if "surgical narcosis" has been employed, and it can therefore reasonably be suggested that they are connected with "mental shock" consequent on operations done on the eyes of elderly persons while conscious.

Orthodox Technique

The most important point in cataract extraction is that the surgeon should leave the face of the vitreous fluid intact. Even if the patient has reasonably good vision afterwards any loss of vitreous during or after the operation is a grave surgical disaster, due practically always to faulty technique. Prolapse of the iris is the most feared post-operative complication, since it necessitates a further and risky operation on a sensitive eye. The first case of prolapsed iris that I had in private practice was due to delirium coming on the day after extraction of the cataract. The patient in her violence ruptured the face of the vitreous, of which much escaped. This case turned my attention to devising methods of increased safety.

When the incision is made in cataract extraction the eye is usually steadied by fixation forceps which grip the friable conjunctiva either at W (Fig. 1) or at X, or at some point between. In either case the active co-operation of the patient is needed to control the eye and prevent the movement of the knife rolling it sideways if the grip is at W, or rolling it upwards if the grip is at X. Some operators insert a length of silk (R, Fig. 3) in the tendon of the superior rectus; this stabilizes the eye to some extent, but not adequately by itself. In the customary procedure the "puncture" (P, Fig. 1) and counter-puncture (P') are outside the limbus (L). The knife (K, Fig. 1) makes a "peripheral" incision cutting out close to the base of the iris so as to create a conjunctival flap (C, Fig. 2) beneath which the incision eventually heals. The

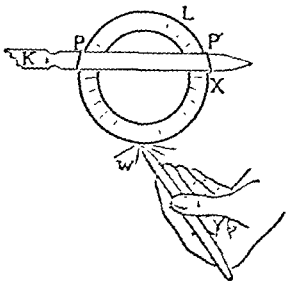

FIG. 1.

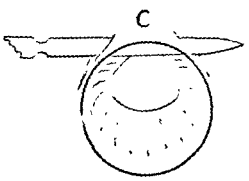

FIG. 2

peripheral position of the incision predisposes to prolapse of the iris, which is not prevented even if the conjunctiva is sutured, as is occasionally done. I prefer to make the incision mainly on the corneal side of the limbus away from the base of the iris.

Surgical Narcosis

In 1934 I used various recognized agents, including bromide and chloral hydrate and rectal paraldehyde; nembutal causes restlessness in some patients. In 1935, after consultation with Dr. R. J. Clausen, Dr. Maitland Scott, and Mr. L. Broster, I decided that rectal paraldehyde was reasonably satisfactory. Later I combined with this a hypodermic injection of omnopon, and the result was excellent. The amount of paraldehyde given—one drachm being dissolved in ten drachms of saline—is three-quarters to one drachm for each stone of the patient's weight, and the dose of omnopon should be one-thirtieth of a grain for every stone (*vide*:—Section of Anaesthetics of the Royal Society of Medicine: "Preliminary Medication in Anaesthetics," December 7, 1928: also "Premedication," *Journal*, October 17, 1931, p. 693, both by Stanley Rowbotham). Bromide is given by mouth in the preceding twenty-four hours. The paraldehyde is given by the rectum an hour before the operation; the omnopon is injected about half an hour before the operation. About three-quarters of an hour before operation some biniodide of mercury ("cust") ointment is placed beneath the eyelids. At the same time two small cotton-wool swabs, soaked respectively in 2 per cent. homatropine and adrenaline 1 in 1,000 (to produce full dilatation of the pupil) are inserted beneath the upper eyelid. The swabs and the ointment are renewed a quarter of an hour before operation, with an additional swab soaked in 1 per cent. cocaine. (I omit here the description of certain customary novocain and adrenaline injections of the eyelids, etc., besides nursing details of the preliminary preparation for narcosis, which is simple.) If less paraldehyde and omnopon is given, so that deep narcosis is not attained, then, despite semi-consciousness,
